LIBRARY
UNIVERSITY OF ILLINOIS
URBANA

INDEX TO VOLUME II., 1925.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (C.M.P.) = Conduct of Medical Practice, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Abattoir Society, Model, B. W. Richardson Lecture at, 1042
Abdomen, The Early Diagnosis of the Acute (Zachary Cope), 3rd edit. (R.), 922
Abdominal adhesions, treatment of (W. Anderson) (M.T.T.), 32
Abdominal lesions, chronic upper, study of family histories of 300 patients suffering from (G. P. B. Huddy), 276; familial (C.), 357, 408
Abdominal levels (A.), 1130
Aberdeen, M.O.H.'s report, 670
Abortion, criminal, in Germany, 620
Abt, Isaac A., editor of Pediatrics, by various authors, Vols. IV.–VI. (R.), 388
Acetylaminophenylarsinic acid "190," *see* Stovarsol
Acetylene, anæsthetic properties of (A.), 558
Acknowledgment, an (C.), 252
Actinomycosis, radium treatment of, 97
Actinotherapy, apparatus for, 681
Addison, Dr., selection of, as Parliamentary candidate, 786
Adenoids among school-children (A.), 391; (C.), 574
Adrenalin, direct injection of, into heart for arrest during anæsthesia (C.), 1208
Adrenals and testes, effect of glycerine emulsion of, on tuberculous and senile patients (V. Korenchevsky), 1056
Æsculapius, the cures of (Ernest A. Gardner), 688

AFRICA, SOUTH, CORRESPONDENCE FROM.—Leprosy Hospital, a central, 570—Maritzburg, South African Medical Congress at, 569—Obituaries, 570

Africa, South, inoculation against cattle disease in (A.), 29; Institute of Comparative Pathology in, 1243
African colonies, medical service in (P.I.), 47; practitioner, South, death of a, 412
Agarol brand compound (R. and A.R.), 872
Agomensin and Sistomensin (R. and A.R.), 976
Agra and Oudh, United Provinces of, public health in, 952
Air embolism during Fallopian inflation (C.), 1306
Air-passages and Mouth, Anatomy, Development, Physiology, Examination (ed. Denker and Kahler) (R.), 810
"A.J.S. Radio" luncheon, 628
Akathisia, 8
Albuminuria, postural (orthostatic), origin and significance of (James W. Russell), 683
Alcock, A. W., The anopheles mosquito in England, 34
Alcohol in Medical Practice (C. C. Weeks) (R.), 506
Alcoholism and tuberculosis, 521; as an international problem (A.), 822; colloidal gold in the treatment of (C.), 1207; recrudescence of, in France, 240; treatment of (Paul Bousfield), 1150
Alexander, John, The Surgery of Pulmonary Tuberculosis (R.), 1120
Alexandra Day, 747
Alimentary tract, radiological studies of, 99
Allen, H. Stanley, Photo-Electricity, the Liberation of Electrons by Light (R.), 1286
Allonal (R. and A.R.), 706
Alpine health resorts, the equable cooling power of (Leonard Hill and Bernard Hudson), 897; thermal station, an (T. N. Kelynack), 1367
Amazon, the river, for tourists (C.), 153
Ambulances at Olympia, 1086; home service (A.), 822
America, medical education in, 39
American convalescent home, an (A.), 613; hospitals (Lionel G. Pearson), 663; Medical Association, annual meeting of, 38; Public Health Association, annual meeting of, 1195
"Americanitis," 1079
Anæsthesia, apnœa, dyspnœa, and cyanosis in relation to, 1283; respiration in (A.), 1184
Anæsthesia, Local: Die Örtliche Betäubung (H. Braun), 7th edit. (R.), 758; The Technique of (A. E. Hertzler), 3rd edit. (R.), 758
Anæsthetic properties of propylene and acetylene (A.), 558
Anæsthetics for dental work (C.), 846; local, and chemical constitution (A.), 709
Analysis, Allen's Commercial Organic (ed. S. S. Sadler, E. C. Lathrop, and C. A. Mitchell), 5th edit., Vol. III. (R.), 181, *and see* Chemical Analysis
Anatomical and Physiological Discovery to Harvey, A Short History of (C. Singer) (R.), 870
Anatomische Praeparieruebungen (Hans Virchow), Curs I. and II. (R.), 506
Anatomy, Applied (G. G. Davis), 6th edit. (R.), 74; Buchanan's Manual of (various editors), 5th edit. (R.), 758; Clinical, Hand-Atlas of (A. C. Eycleshymer and Tom Jones) (R.), 1174; Short History of (Richard H. Hunter) (R.), 1174
Anderson, Henry Græme (O.), 43
Anderson, William, Treatment of abdominal adhesions (M.T.T.), 32
Angina pectoris, surgical treatment of, 883
Animal pathology and physiology (A.), 343
Animals, Council of Justice to, annual report, 632; Diseases of, Bill (P.I.), 207, 259, 307
Anopheles mosquito in England (A. W. Alcock), 34
Antenatal care: The case for the unborn child (T. Watts Eden), 1153; 1218
Anthropology and preventive medicine (A.), 79
Anthropology: Human Constitution (G. Draper) (R.), 74; Measurements, Weights, and Other Facts Relating to Man (J. F. Tocher) (R.), 74
Anthropology, Physical, A Short Course of (M. R. Drennan) (R.), 74
Antityphoid and anticholera inoculation in Europe (A.), 1080
Aortitis, prognosis and treatment, 1120
Aphasia: Kritische Studien zur Methodik der Aphasielehre (E. N. von Mayendorf) (R.), 1121
Appendicitis, gangrenous: the initial syndrome (C.), 1305; Interpretacion de las Apéndicitis, Indicaciones Operativas (Juan Mariñon) (R.), 650
Appetites, anomalous (L.A.), 818
Apple-tree sprays, poisonous (P.I.), 1312
Apples, arsenic in (A.), 1295; danger of insecticides on (P.I.), 47
Applicant, an unregistered (C.), 52
Appointments, weekly lists of, 49, 107, 161, 211, 261, 311, 361, 412, 527, 578, 629, 678, 730, 787, 844, 896, 948, 999, 1044, 1099, 1149, 1204, 1262, 1314, 1367
Approved societies, accumulated funds of: deputation to Minister of Health, 209; valuation of (P.I.), 208
Armstrong, E. A. (O.), 891
Army, ill-health in the (P.I.), 1311; in the field, health of an, 1264; pharmacy in the (P.I.), 260, 1258, 1260; tinned food in the, 673
Arsenic in apples (A.), 1295; use of, in puerperal fever (A.), 28
Arthritis, chronic, discussion on, 601; rheumatoid, discussion on, 327
Artificial light and X ray therapy in Scottish hospitals, 1345; limbs, supply of (P.I.), 1145
Artist, technique of the, 1102
Ascaris lumbricoides and pigs (C.), 523; in Hertfordshire (A.), 138
Ashanti, health reports from, 789
Association Stomatologique Internationale, meeting of, 195
Asthma, treatment of, discussion on, 600
Athletic records, the physiological basis of (A. V. Hill), 481
Athletics and economy (A.), 879; sugar and (L.A.), 611; (C.), 790
Atkinson, the late Dr. A. W., 412

AUG 30 '26

609627

Atmospheric dust, the measurement of (A.), 712 ; pollution (A.), 81
Atrophy of renal origin in a young infant (C. Chisholm and E. F. Willock), 701
Atropine and the total alkaloids of belladonna, comparative action of, 241
Australian health bulletin, an (A.), 980
Austria, public health, administrative machinery in, 718
Avenues in medicine (Sir Charles Sherrington), 741

THE
Origin and Significance
OF
POSTURAL (ORTHOSTATIC) ALBUMINURIA.

BY JAMES W. RUSSELL,* M.D. CAMB.,
F.R.C.P. LOND.,

PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL; JOINT PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BIRMINGHAM.

BY the term postural (or orthostatic) albuminuria I mean nothing more than an albuminuria which develops in the upright position and ceases when the patient lies down. It is commonly used to imply a special form of albuminuria, "functional" or mechanical in origin, constituting a more or less defined clinical condition and tending to affect a special type of patient—children or young adults, often of poor physique, with low blood pressure and cold extremities, excreting globulin in excess of albumin. Whilst admitting the convenience of using the name only for the cases in which urine secreted in bed is free from albumin, I do not agree that the condition is always "functional" in nature, or is to be found in any particular type of patient, and I think that the limitation of the conception of the effect of posture on albumin excretion to the cases in which the bed urine is entirely free from albumin robs the symptom, as I would prefer to regard it, of much of its significance. The object of this paper, the outcome of five years' study of the subject, is to bring forward evidence in favour of the view that many cases of purely orthostatic albuminuria are the result of infection, and secondly to establish the point that the orthostatic reaction, in the true sense of the term, is common alike to the supposedly functional cases and to most, if not all, cases of nephritis, and, indeed, possibly to most forms of albuminuria.

In the *Quarterly Journal of Medicine*, January, 1923, I published a study of a series of cases of orthostatic albuminuria, based upon graphic records of the albumin output. The results were not altogether in accordance with the views usually held as to the functional nature of these cases, and it was especially noted that the orthostatic response, in nearly all its features, was met with in certain cases of mild nephritis. On this, as well as on other grounds, the provisional suggestion was made that orthostatic albuminuria might, in some instances at any rate, be the outcome of a past renal infection of mild degree. Since writing that paper I have continued to investigate all the cases of the condition occurring in my wards and in private practice, and I have now some fresh evidence to offer in support of the suggestion.

METHOD OF MEASUREMENT OF ALBUMIN.

The albumin measurements recorded in the *Quarterly Journal* and in the present communication have all been obtained by the method of estimation described in detail in the former paper, and more briefly in THE LANCET of Oct. 27th, 1923. Its advantages are that it makes possible the measurement of any quantity of albumin, down to the smallest trace. It would take too long to repeat here the description of the method. I may merely say that it depends upon the number of dilutions needed to reduce a cloud of coagulated albumin to the point at which it matches a standard haze. Further that the standard I now use is made by mixing together half a cubic centimetre each of a 0·014 per cent. solution of barium chloride and magnesium sulphate respectively, and adding, after the haze has developed, 10 c.cm. of distilled water pigmented so as to imitate the colour of a pale urine. (The solutions are kept in bottles previously treated with strong hydrochloric acid in order to neutralise the alkali of the glass.) The haze so produced constitutes the "unit" of albumin, and is practically the smallest haze recognisable in a good light against a dark background. For various reasons it is inadvisable to assign to the unit any absolute value. The object aimed at is the study of the relative output of albumin under different conditions and at different times; the absolute amount passed is rarely a matter of importance. Indeed, it is open to each observer to work with the unit with which he feels that he can obtain the most accurate results, and with myself this is the smallest recognisable haze. Although, in order to save reproduction, only two charts are included in this paper, all the cases recorded have been studied by means of exact observations obtained in this manner.

THE ORTHOSTATIC REACTION.

I will not burden my paper with any long account of the natural history of the orthostatic reaction. It will be enough to enumerate the chief features, as follows: The urine secreted in bed is ordinarily free from albumin, whilst that of the upright position is more or less albuminous, the amount of albumin varying directly with the time spent in the upright position, and in inverse direction, though not, I think, exactly in inverse amount, with the quantity of urine in process of secretion. Artificial lordosis, produced in bed by means of pillows, may or may not give rise to the passage of albumin, but standing upright usually, and standing in the position of lordosis invariably, produces an albuminuria, except during a period of diuresis. Standing in the leaning forward position abolishes the excretion of albumin.

SOURCES OF FALLACY.

There are two sources of fallacy with which I must deal before recording my evidence, inasmuch as they often interfere with the recognition of cases that are strictly orthostatic in nature, and one, at least, may easily lead to misinterpretation of my results.

(1) It is usually held that the urine passed immediately on getting out of bed by a patient suffering from orthostatic albuminuria is invariably free from albumin, and that any deviation from this behaviour excludes the case from the orthostatic group. But this statement is untrue of many genuine cases, and for an obvious reason. The albuminuria set going by the upright position continues, and sometimes increases, for half an hour or more after the return to bed, and Chart 1 shows what often happens when a patient, the subject of a postural albuminuria, gets out of bed, stands for a few minutes, and then resumes the lying-down position. In this case a boy with an obvious orthostatic albuminuria got out of bed and passed albumin-free urine. He then stood for seven minutes, returned to bed, and passed urine as soon as possible afterwards. This urine was highly albuminous. Twenty minutes later he again passed urine, being still in bed, and this urine was yet more albuminous than before. An hour after the return to bed a trace of albumin was still present. An actual increase in the albumin excretion on lying down does not always occur, and probably does not take place at all when the patient goes to bed at the end of the day with a definite albuminuria. (This he generally does, for the cessation of the albuminuria during the late afternoon and evening, supposed to characterise the orthostatic cases, is, according to my experience, altogether the exception.) But the albuminuria with which he goes to bed continues for half an hour or more after lying down, though gradually diminishing, and the retention in the bladder of this albuminous urine contaminates the night's collection and registers itself in the morning urine as a definite haze. The case is then apt to be wrongly rejected as one in which the albuminuria is not of the orthostatic variety.

This point is of sufficient importance to bear illustration by two cases.

---

* An obituary notice of the late Dr. Russell, who died shortly after this paper reached us, appears in another column.—ED. L.

A lad, aged 16, in whom an albuminuria had been discovered on routine examination preliminary to application for admission into the Air Force, was admitted into the Birmingham General Hospital under Dr. L. G. Parsons, to whom I am indebted for the opportunity of examining him. The albuminuria had been regarded as almost certainly of the postural variety, but a small amount of albumin had been persistently present in the night's collection of urine—he was up and about all day. On May 2nd–3rd the following observations were made :—

	c.cm. urine.	Albumin units.
9 P.M.—On going to bed	20	375
11 P.M.—Two hours after lying down	120	18
7 A.M.—On getting up	230	0
9 A.M.—Two hours up	30	220

On this occasion the bladder was emptied afresh two hours after going to bed and the morning urine was then free from albumin. Had the 11 P.M. urine been retained, the morning specimen would have contained from 6 to 7 units of albumin, a small, but quite recognisable haze.

CHART 1.

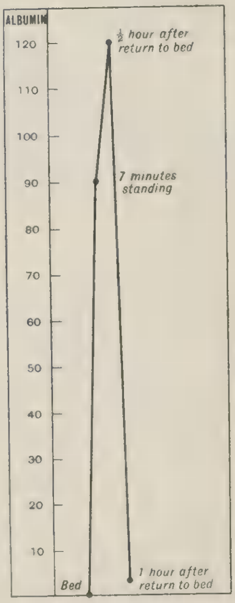

CHART 2.

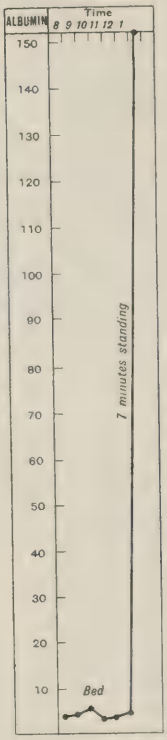

The second case was that of a girl, aged 11, who was in my ward in May, 1924, with a postural albuminuria of large degree. A year later she was readmitted for further investigation, and now the morning urine regularly contained a haze of albumin. But on April 11th, after being up all day, she went to bed with an albuminuria of 90 units, and an hour later was made to pass urine again. Next morning the night's collection was entirely free from albumin.

This source of fallacy will receive further illustration in others of my cases. It is one that is not, I think, generally recognised, but unless it is kept in mind many strictly orthostatic cases will pass undiagnosed.

(2) The second source of fallacy lies in the fact that during diuresis the upright position loses its effect on the excretion of albumin. For this reason in a suspected orthostatic case it is never safe to depend upon the absence of albumin from a single plentiful specimen of urine. And even in the absence of diuresis it must always be remembered that the sitting posture also abolishes the albuminuria.

INFECTIVE ORIGIN OF MANY CASES OF ORTHOSTATIC ALBUMINURIA.

In the paper already referred to the first case studied was that of a girl in whom the albuminuria had first been discovered immediately after an attack of diphtheria. I have now to bring forward evidence pointing to a connexion between the orthostatic condition and a past attack of scarlet fever. I am aware that the origin of the condition in a former attack of scarlatinal nephritis has often been suggested, but, as will be seen, that is not exactly my contention.

CASE 1.—I am indebted to Dr. H. Savage, my former house physician, for bringing this case to my notice, and for permission to publish the details. The patient was a girl, aged 8, who was seen by him when in practice in Coventry. Two months previously the child had been admitted into the Fever Hospital with an attack of scarlet fever, and she was discharged at the end of six weeks, without any known abnormality of the urine. A week after her return home she was brought to Dr. Savage with œdema of the left leg and the left side of the face ; the urine contained a thick cloud of albumin, and casts were found in the deposit. The girl was put to bed, and the œdema and albuminuria at once came to an end. After a further period of rest in bed the œdema did not return on getting up, but from that time, whilst the bed urine was invariably free from albumin, 10 minutes' standing always produced a definite cloud. On Dec. 2nd, 1923, some four months after the onset of the fever, two specimens of urine were brought to me for examination. One, passed immediately after getting out of bed in the morning, was quite free from albumin. The other, passed soon after standing upright for 10 minutes, contained 110 units, a fairly thick cloud. On occasions, during the next 12 months, further specimens were examined with the same result, but by the end of 1924 the immediate response to standing had practically ceased. Whether or not the urine of the rest of the day was albuminous I do not know, as the case passed out of reach.

CASE 2 was that of a young man, aged 25, who contracted scarlet fever in the army in 1918. He was treated for six weeks in the Fever Hospital, and was discharged without any suspicion of renal disease. A fortnight later he was examined for some routine purpose and albumin was discovered in the urine, and eventually he was discharged from the army with the diagnosis of nephritis. From that time onwards his doctor had found an "intermittent albuminuria." He consulted me in May, 1925. The blood pressure was 85/142, but I thought that the rather high systolic reading might be partly the result of excitement. The heart was not recognisably enlarged and I could find no casts in the urinary deposit. On May 23rd he sent me a series of specimens of urine passed at hourly intervals throughout the morning, together with one passed on going to bed the night before, with the following results :—

	c.cm. urine.	Albumin units.
11 P.M.—On going to bed	42	90
8 A.M.—On getting up	300	6
9 ,, ...	35	70
10 ,, ...	46	65
11 ,, ...	40	70
12 noon	55	36
1 P.M.	50	28

The trace of albumin in the early morning specimen is easily explained by the fact that the urine was heavily loaded at bedtime the night before, and the bladder had not been emptied again during the night.

The two following cases suggest that a definite scarlatinal nephritis may ultimately be represented by a postural albuminuria.

CASE 3.—A girl, aged 13, was sent into my ward on account of an albuminuria discovered in the out-patient room. Two years previously she had had an attack of scarlet fever and her mother was informed that the kidneys were slightly affected and that the urine was "not quite right." The albuminuria was entirely postural in occurrence, though the immediate response to standing was but slight.

CASE 4 was that of a young man, aged 24, who consulted me for "nephritis." At the age of 10 he had had an attack of scarlet fever which was not at first diagnosed. In consequence he went about for some days and a nephritis developed. From that time albumin had been almost always found in the urine, and a year ago a very serious prognosis had been given. When I saw him in May, 1924, he was somewhat pale and complained of being easily tired. The heart was not enlarged and the blood pressure was 80/130. The urine passed in my room contained a cloud of albumin, but neither in this specimen nor in others subsequently examined was I able to find any casts. Next morning the urine passed on getting out of bed contained 8 units of albumin, and 10 minutes' standing produced a dense cloud of over 500 units. On other occasions the same trace of albumin was found in the bed urine, but that this was due to the continued excretion of albumin during the first period after getting to bed at night is shown by the fact that on one occasion when the bladder was emptied afresh an hour after lying down the urine next morning was absolutely albumin-free.

Post-Scarlatinal Orthostatic Albuminuria.

These cases seem to suggest, not only that a scarlatinal nephritis may eventually be represented by a postural albuminuria, but that the same condition may sometimes occur after an attack of scarlet fever in which no question as to the soundness of the kidneys has been raised during the period of retention in bed, and I thought that some further information might be obtained at the fever hospital. I accordingly took the problem to Dr. E. H. R. Harries, the medical superintendent of the Birmingham Fever Hospitals, and he most kindly gave me every facility for investigating the matter. He referred me to Dr. W. M. MacFarlane, the medical superintendent of the Lodge-road Scarlet Fever Hospital, to whom I am much indebted for placing two children's wards at my disposal, as I am also to the sisters and nurses in charge of the wards for much trouble taken in procuring the necessary specimens. Dr. MacFarlane allowed me to examine a series of specimens of urine passed some three hours after getting up in the morning by a number of children convalescent from scarlet fever, none of whom had shown any sign of albuminuria so long as they had remained in bed. On the first occasion on which this was done 16 urines were collected for my examination, and of these four contained a material quantity of albumin. Three of the albuminurias proved to be fleeting; at any rate, no albumin was discovered in any of the three two days later. But the fourth gave on that day a definite response to the standing test, the bed urine being albumin-free, and an hour later a larger albuminuria had developed. This boy went home next day, the subject, for the time at all events, of a moderate postural albuminuria.

I have now examined the urines of 83 of these children, the conditions being exactly similar in each case. Of these 83 urines, 22 contained a considerable quantity of albumin on the first examination; I have omitted several others in which the amount of albumin was very small. Seven of the 22 patients went home to my knowledge with an albuminuria of the orthostatic type, found to be present on more than one occasion, and I have added to the list five others in whom discharge from hospital prevented me from making more than one examination. The rest I have discarded—three because no albumin was found on a second examination, and others because the second examination showed only a small amount. In discarding all these I am probably altogether understating my case, for a single negative or slight result is rarely safe ground for excluding an orthostatic albuminuria, but it is better to err on that side. What has especially struck me has been the unvarying regularity with which these albuminurias have been found. I paid in all nine visits to the fever hospital and examined on an average nine urines at each visit. There was not a single occasion on which I did not obtain from two to four or more positive results. As will later be stated, such results have not been obtained in examinations made in other conditions. Particulars of the cases that have not been discarded are as shown in the table fo'lowing.

The slight bed albuminurias noted on single occasions in Cases 3, 4, 5, and 7 have probably the usual explanation of contamination by the albumin excreted shortly after getting to bed the night before, for in all these cases on another day, or on other days, this urine has been found to be free from albumin. Case 9, with a slight bed albuminuria, rests on a single examination, but the same explanation probably holds. It has not been possible, however, to put the explanation to the proof which I have applied to such cases in my own wards. It is further to be regretted that I have not so far been able to follow up the after-history of these cases. There are considerable difficulties in the way, but, should opportunity offer, I shall avail myself of it. It may be, of course, that some or even all of the albuminurias may have cleared up after the return home, and this gap in the evidence is unfortunate. But the results may fairly be looked at in connexion with the first and second of my recorded cases. In these an exactly comparable orthostatic albuminuria was discovered a week and a fortnight respectively after discharge from hospital, and the albuminuria is known to have persisted for at least a year in the one case and for seven years in the other.

No. of case.	—	Units of albumin in bed urine.	Units of albumin after getting up.

These cases seem to establish the fact that patients who have passed through an attack of scarlet fever without showing any albuminuria so long as they remain in bed, not infrequently develop, at any rate for a time, an orthostatic albuminuria on getting up. The interpretation remains for discussion. Four possibilities occur to me—there may be others of which I have not thought. The explanation may be one of coincidence, and all these patients may have been the subject of an orthostatic albuminuria previous to their attack of scarlet fever. Or, again, it may be that in any series of children getting up after a few weeks' illness in bed, a certain number will develop a temporary postural albuminuria—a sort of protest by the kidney against resuming work under harder conditions.

The only way of testing the truth of these suggestions is by examining a control series of children, roughly of the same age, convalescent from illnesses other than those due to specific infections. This I have attempted to do, but it has been difficult to obtain any material number of suitable cases, and for most of those that I have been able to examine I am indebted to my colleague, Dr. K. D. Wilkinson, who has found them for me at the Children's Hospital. I have now examined 35 cases and have found amongst them three instances of albuminuria of the orthostatic type. Two of these children had been in the fever hospital a few months previously with an attack of scarlet fever, and may, I think, fairly be excluded. The third had an active suppuration of the glands of the neck, and was therefore not really convalescent from her infection. If I accept this case as an example of coincidence and not the result of infection, I get a percentage of 3·1 positive results amongst these children, as compared with one of 26·5 amongst similar single examinations made in the convalescent scarlet fever cases. If I give the decision wholly, and, I think, wrongly against myself, and include the two children who had recently been discharged from the fever hospital, the percentage is 8·6 against 26·5. I do not think, therefore, that either of the above suggestions will account for my results. I suppose that a third explanation might lie in some obscure vaso-motor effect of the scarlatina. But such an explanation seems too vague for serious discussion, unless one starts out with the assumption that orthostatic albuminuria must necessarily be functional in nature, and it is this assumption that I am combating.

The only other explanation that I can see is one that falls in with the impression that has gradually grown up in my mind as the result of a long study of the orthostatic reaction—namely, that this type of albuminuria is in many cases the expression of a past renal infection of mild degree, and the suggestion would then be that in these post-scarlatinal postural albuminurias we are meeting with the very smallest degree of infection of the kidney. The conception of an infection so slight that it never translates itself into an albuminuria so long as the patients are kept in the horizontal position may seem far-fetched, but I can see no inherent impossibility in the idea. It postulates a damage to the kidney far short of anything so far described in the post-mortem room, but such degrees of damage must surely exist. Whatever the explanation, the facts are as I have stated them.

My results raise a further question—namely, whether it is not possible that cases of orthostatic albuminuria, with no known history of scarlet fever, may yet have had a scarlatinal origin. Dr. Harries tells me that in his opinion many cases of scarlatinal infection probably pass unrecognised as an "ordinary" sore-throat without rash. If that is so, the absence of a history of scarlet fever in genuine post-scarlatinal orthostatic cases would be easy to understand. We are accustomed to speak of the "adolescent type" of albuminuria, as though it were only to be expected that the adolescent kidney should at times leak albumin. I see no reason why the adolescent kidney should behave in this manner, but I do recognise that childhood and adolescence are the periods of special susceptibility to specific infections.

THE CONNEXION BETWEEN ORTHOSTATIC ALBUMINURIA AND PREVIOUS SCARLATINAL NEPHRITIS.

The connexion between orthostatic albuminuria and a past attack of scarlatinal nephritis has been previously suggested. Bass,[1] in 1912, gave an abstract of three papers dealing with the subject. Weiss-Eder [2] allowed 40 children with scarlet fever to kneel in a position of lordosis, with the result that 23 developed an albuminuria. The writer concludes that children convalescent from scarlet fever are not more disposed to nephritis than other children, and that such children, having nephritis, often show an orthostatic albuminuria, "which may be due to weak muscles." Nothman [3] found that 12 out of 13 cases of scarlet fever in which at an earlier date the lordotic experiment was positive, albumin appeared later in the urine, but that in those in which lordosis did not cause albuminuria, albumin never appeared spontaneously later on. He concludes that, just as nephritis may terminate in orthostatic albuminuria, so conversely an orthostatic albuminuria may be the first sign of nephritis. Schick[4] says that orthostatic albuminuria following scarlet fever has a good prognosis, and refers to Jehle, who examined 17 children in various stages of scarlet fever. In 12 there occurred a marked albuminuria in the position of lordosis, upright and prone, but none developed a nephritis. In each case I quote from Bass's abstract.

On the other hand, Hansborg,[5] of the Blegsdam Fever Hospital, Copenhagen, after a very careful study of the after-history of a large number of patients who had suffered from scarlatinal nephritis, rejects the idea that there is any special connexion between such nephritis and the subsequent development of orthostatic albuminuria. Among 226 children and young people, who had all had scarlatinal nephritis, he found 23 (10 per cent.) with orthostatic albuminuria, "which is even a lower figure than is generally quoted in examinations of arbitrarily chosen individuals of the same age" (I quote from a translation). I gather, therefore, that Hansborg looks upon these patients as likely to have been the subjects of an orthostatic albuminuria previous to their attack of scarlet fever. While holding that no single explanation hitherto propounded accounts alone for the condition, he supports the usual view that lordosis plays, at any rate, a chief part in its causation, though he admits that in only 6 of his 23 cases was a "pathological" lordosis to be discovered. But, he adds, "what can be considered as pathological here must be a matter of expert opinion."

While it is desirable to include a reference to these various opinions, it is to be noted that they largely deal with two matters with which my paper is not particularly concerned—namely, the occurrence of orthostatic albuminuria as the result of scarlatinal nephritis, and the effect of artificial lordosis in patients convalescent from scarlet fever. My point is that this type of albuminuria appears to develop on getting up in patients who have not shown any sign of nephritis during rest in bed, and for this it has not been necessary to assume any position of lordosis, which, after all, is only the extreme of the upright position. That lordosis is the essential cause of orthostatic albuminuria I do not believe. The evidence in its favour has never seemed to me very conclusive, and so many of my cases have shown an absence of material lordosis on X ray examination that I have long discarded it as an adequate explanation. Hansborg's cases, again, hardly seem to afford it much support. It may be, however, that there is a type of case into the causation of which it enters, as suggested at the end of my paper.

INFECTIONS OTHER THAN SCARLATINAL.

I come now to infections other than scarlatinal. I have already alluded to a case in which the condition was discovered immediately after an attack of diphtheria, and Dr. Chalmers, of the Little Bromwich Fever Hospital, very kindly collected for me one day the urines of 18 children convalescent from diphtheria; out of over 300 cases then in hospital these were the only ones in which no albumin had been discovered during the bed period. The children had all been up three hours, and the urines were therefore strictly comparable to those of the scarlet fever series. In these 18 urines I found one with a big albuminuria (560 units) in the upright specimen, the bed urine being albumin-free. One other urine showed a trace of albumin comparable to those discarded in the scarlet fever cases. These observations are again opposed to the explanation of the post-scarlatinal orthostatic albuminurias on the ground of coincidence. I know of a man, 49 years of age, with a postural albuminuria who dated his condition from an attack of syphilis occurring many years previously, and I have come across the case of a woman with an albuminuria of the same type who had had eclampsia two years ago. But both of these cases rest on a single examination only, and I cannot attach any great importance to them. Lastly, I have under observation two boys who were in my ward with a mild attack of acute nephritis of ordinary type, and who left hospital with a bed urine that was almost free from albumin and a big upright albuminuria. They were readmitted for 24 hours, three and two years respectively after their acute attack. In one the bed urine was nearly, but not quite, free from albumin; in the other no trace of albumin was found in the bed specimen. Both developed a large albuminuria immediately on getting up. While, therefore, I think that there is a special tendency for orthostatic albuminuria to develop, at any rate for a time, in patients getting up after an attack of scarlet fever, I am far from holding that the reaction is specific to that infection.

[5] Acta Medica Scandinavica, Feb. 12th, 1925.

Two further points have impressed me as possibly bearing on the question of the infective origin of orthostatic albuminuria. The first is the frequency with which cases come under notice on account of symptoms of ill-health. A certain number of my cases have been discovered on routine examination for some purpose or other, but the majority have come complaining of headache, fatigue, lassitude, and occasionally some little swelling of the face. With a few days' rest in bed these symptoms have disappeared or a slow improvement has taken place. Secondly, it not uncommonly happens that a case in which such symptoms are present on admission shows at first an exaggerated response to the upright position, which also diminishes with rest in bed. For example, a boy, aged 13, was admitted from the out-patient room complaining of general ill-health. On Nov. 29th, 1924, seven minutes' standing gave rise to an enormous albuminuria (650 units), whilst on Dec. 1st eight successive hourly specimens passed in bed were all entirely free from albumin. A fortnight later he was up with quite a moderate albuminuria—a maximum of 40 and 50 units, whilst standing now produced but a small response. But I would add that the variations in the response to the upright position in these cases are often so extraordinary that I must not attach too much importance to an apparent improvement such as is shown in this case. It may be that a few more observations would have upset the conclusion, and I have one case in mind in which a similar apparent improvement was suddenly reversed during the patient's stay in hospital.

RELATIVE PROPORTIONS OF GLOBULIN AND ALBUMIN.

I may briefly refer to the question of the preponderance of globulin over albumin in the urine, almost universally accepted as marking off the orthostatic cases from those of albuminuria of organic origin. My experience does not support the distinction. Certainly, if it holds, the organic nature of most of my cases of orthostatic albuminuria is definitely proved, but the relationship seems to me altogether too variable for use in diagnosis. I am far from denying that in the great majority of cases of nephritis albumin is enormously in excess of globulin, but I have come across a few cases of definite acute nephritis in children in which the reverse relationship has been present. On the other hand, of 11 apparently non-scarlatinal cases of orthostatic albuminuria in which I have kept notes on the point, in four globulin was in excess, and in the remaining seven a big excess of albumin was registered. In the scarlatinal cases examined at the fever hospital the same inconstancy of relation was noted. Two of the urines showed an undoubted excess of globulin, but in most of the others there was an equally undoubted preponderance of albumin. I did not, however, remember in every case to make the necessary observations. Each of the two positive diphtheritic cases showed an excess of globulin.

POSTURAL ALBUMINURIA A SYMPTOM.

I began by stating that I would regard postural albuminuria as a symptom only, and that the limitation of the term to the cases in which the bed urine is entirely free from albumin, convenient as it may be, tends to rob the symptom of much of its significance. The fact is that in many, and possibly all, forms of albuminuria the albumin output is susceptible to the influence of posture, though in very varying degrees in different cases. This is, I think, certainly true of the "parenchymatous" varieties of nephritis, acute and chronic, and several of the charts published in the *Quarterly Journal* show an albuminuria in mild acute nephritis which came down to a very small amount with the patient in bed, but was present in gross quantity in the upright position. I would therefore regard the complete cessation of albumin excretion in the horizontal position, characteristic of "orthostatic albuminuria," merely as the extreme example of the influence of posture. The following records are taken from the case of a man with chronic nephritis, a somewhat raised blood pressure, and numerous casts in the urine :—

	Albumin units.	
On going to bed	1100	
One hour after going to bed ..	120	(urine plentiful)
On getting up next morning ..	550	(urine concentrated)
Three hours after getting up ..	700	
Seven hours after getting up ..	1275	

The very big drop in albumin content an hour after going to bed is to be somewhat discounted by the fact that during the hour a plentiful urine was secreted, and, on the other hand, the relatively high morning reading is largely accounted for by the concentration of the urine of the rest of the night, due, of course, to the absence of fluid intake. But the influence of posture seems undeniable. Whether this influence is exerted in the chronic interstitial types of nephritis I am not so certain, but this is a matter which I have not carefully investigated.

Finally, cases are met with in which the albuminuria is almost, but not quite, "orthostatic" in nature, and these seem to me to form a possible connecting link between the completely orthostatic cases and cases of nephritis responsive to posture. Chart 2 (p. 684) gives an example of such a case. The patient, a boy aged 14, was in fairly good health when one day he fainted at school. Examination of the urine showed a large cloud of albumin, and he was put to bed, with the result that the albuminuria at once very nearly came to an end, but never quite ceased. When I saw him he had been in bed for some weeks. The blood pressure was a shade high for the age (130, systolic), but no casts were at any time found in the urine. As shown in the chart (one record out of many is alone included), he was intensely sensitive to the upright position, and seven minutes' standing always produced a big response. When he got up in the morning a very large albuminuria developed, but getting up in the afternoon gave a much smaller result—an approach to the "cyclical variation." Yet the bed urine invariably showed a slight albuminuria. It is difficult, I think, on this ground to separate the case from the more complete forms of postural albuminuria.

I do not claim that all cases of orthostatic albuminuria have the same or a similar origin. I believe that cases exist in which the symptom is due to mechanical embarrassment, possibly of the left renal vein, and in THE LANCET of Oct. 27th, 1923, I have myself recorded a case of unilateral œdema with an albuminuria probably coming from one kidney only, for which I suggested a purely mechanical explanation. Will it eventually be found that the cases of mechanical origin are those in which the albumin comes from one kidney only ? A certain number of cases of orthostatic albuminuria have been recorded in which catheterisation of the ureters has demonstrated that this was the case. I have some suspicion that these may prove to be the really "functional" cases, and that they own a totally different pathology from that of the cases dealt with in this paper. It may be that here lordosis is of importance. I may add that in five of my orthostatic cases I have tried by postural experiments—standing leaning first to one side and then to the other—to obtain evidence of the unilateral origin of the albuminuria, but in none has there been any material difference in the results.

SUMMARY AND CONCLUSIONS.

1. Many patients suffering from scarlet fever, who present no albuminuria during the period of rest in bed, develop an orthostatic albuminuria immediately after getting up. Some, at any rate, of these albuminurias persist for a considerable time, or even permanently.

2. Some cases of recognised scarlatinal nephritis are ultimately represented by an albuminuria of the orthostatic type.

3. Orthostatic albuminuria may follow other forms of specific infection, or even, though rarely, arise as the end-result of a mild acute nephritis of ordinary type.

4. The proportions of serum globulin and serum albumin are not constant in cases either of orthostatic or nephritic albuminuria, and do not enable a differential diagnosis to be made.

5. It is suggested that in many cases the orthostatic reaction is the result of slight renal damage. But cases probably exist in which the reaction is the result of mechanical causes. As a matter of speculation, it is suggested that in these cases the albumin comes from one kidney only.

6. Some response to posture occurs in most cases of nephritis, and possibly in all forms of albuminuria. All degrees of diminution of the output of albumin during rest in bed are met with, down to the complete cessation of the typical orthostatic cases.

7. Orthostatic albuminuria is probably of more frequent occurrence than is generally supposed. It may pass unrecognised owing to (1) the presence of a small quantity of albumin in the morning specimen of urine, due to the continuance of the upright albuminuria for half an hour or so after going to bed the night before, and the consequent contamination of the night's collection; (2) the cessation of albumin excretion during diuresis, even in the upright position; and (3) the cessation of albumin excretion in the sitting position. Extreme variations in the albumin output, with at times complete cessation, are therefore to be expected.

An Address
ON THE
CURES OF ÆSCULAPIUS.

Delivered to the Students of Westminster Hospital at the Opening of the Winter Session

BY PROF. ERNEST A. GARDNER, LITT. D.,
VICE-CHANCELLOR OF THE UNIVERSITY OF LONDON.

AN interesting chapter in the history of ancient medicine is offered by the cures of Æsculapius, or Asclepios, as the Greeks called him; and the subject is one upon which the students of medicine and archæology meet upon common ground. It has been much discussed whether the priests and descendants of Asclepios, the Asclepiadæ, were the depositories of a traditional skill in medicine and surgery; and in this connexion we must remember that Hippocrates himself was one of the Asclepiadæ, of Cos. The remains of an enormous plane tree in the market-place of the town are still shown to visitors as the place where he gave consultations to his patients The sacred precinct of Asclepios at Cos is situated in a delightful position on a terrace overlooking the sea, and there it is still possible to trace the remains not only of temples and altars, but also of the rows of cells which must have served as quarters for the invalids who came to consult the god or his attendants. Many such shrines of Asclepios existed upon various sites in ancient Greece, most of them in similar positions and surroundings. But two of these are of especial interest to us because we have actual records in literature and inscriptions of the method of consulting the god and the means by which cures were effected. These two are at Athens, where the precinct underneath the south side of the Acropolis referred to by Aristophanes may still be seen; and at Epidaurus, where there have been found not only the remains of the buildings, but two of the six great slabs mentioned by the traveller Pausanias as recording the cures effected by the god.

These two precincts of Asclepios were very similar in their arrangement, though that at Epidaurus was by far the more extensive. Both alike contained more than one temple and one great altar of sacrifice, as well as springs or sacred wells. But the most distinctive building in each was a large portico in two floors, partly closed and partly open to the air, and it was in this building, called in inscriptions the "abaton," that patients who came to be cured spent the night. How they spent it may be partly judged from the well-known description in the Plutus of Aristophanes; for though this description is of course burlesque, and may well appear lacking in reverence, it must have had sufficient resemblance to what actually took place to give point to the jests. In the play Plutus (Wealth) is represented as blind, and his friends resolve to take him to the shrine of Asclepios in Athens "to help him of his blindness." The slave Karion, who attends him during his visit, gives a full account of it, which may be summarised as follows:—

> "First we took him to the sacred spring and washed him; then we entered the precinct of the god, and after offering cakes and the other preliminary sacrifices, we duly put him to bed, among a number of others suffering from divers diseases, and we ourselves had shakedowns beside him. Then a minister of the god came in and put out the lights and bade us go to sleep, and keep silent if we heard any sound. So we all lay quiet. But I could not get to sleep, and I saw the priest going round the sacred tables and altars, picking up the figs and cakes and consecrating them into a bag. Then the god appeared, accompanied by his two attendant maidens, Iaso and Panacea. I hid my head under my cloak in fear, but I watched through the holes in it. And I saw the god going the round of the cases in due order, and an acolyte set beside him a stone pestle and mortar and a medicine chest. He first approached Neoclides, a blind man who excels those who can see at thieving, and he mixed and ground an ointment for him of garlic and fig-juice and squills with vinegar, and anointed his eyelids, turning them back to increase the smart. And the patient shrieked and cried out and tried to run away; but the god laughed and told him to sit still with his plaster. Then he came to Plutus and sat beside him, and first he felt his head, then he took a clean napkin and wiped his eyelids; and Panacea covered his head and face with a purple cloth. Then the god whistled, and two enormous snakes issued from the temple and gently crept under the cloth, and as it seemed to me, licked round his eyelids; and immediately Plutus stood up with his sight restored; and I clapped my hands for joy, and the god vanished with his snakes into the temple. And those who were lying beside Plutus congratulated him and remained awake all night till dawn."

Here we see many of the incidents that are repeated in the records of the cures at Epidaurus; but there is some confusion in both cases as to what actually took place and what was seen in a vision or a dream. But in the Plutus it seems distinctly to be suggested that the priest of Asclepios actually personated the god, a custom not at all unusual in Greek religion; and we know from other sources that large snakes were usually kept in the shrines of Asclepios, and were even in some cases regarded as the god himself.

ANCIENT GREEK RECORDS.

Before proceeding to enumerate the cures recorded at Epidaurus, a few words must be said as to the documents on which they are recorded. These are large slabs of marble headed "Cures of Apollo and Asclepios," discovered and first edited by M. Cavvadias, the Greek Inspector-General of Antiquities. Among medical authorities who have written about them, I would especially mention Sir Clifford Allbutt, Dr. Caton, and Dr. Alexander Cavvadias, son of their discoverer. The slabs were inscribed some time about 300 B.C., but they cannot be regarded as contemporary records of cures. They were evidently compiled at one time, and as we shall see, the source from which they were derived was partly the votive offerings with inscriptions that had been set up by the patients to testify their gratitude to the god, and partly the traditions of the temple; and the fact that one of the most curious cases is recorded by a Greek writer of nearly 200 years earlier in a slightly different form shows that this temple tradition did not deal only with recent cures. Such stories doubtless improved by repetition. Whether some of them had a basis of fact or not is a matter as to which I express no opinion. But, in a general way, many of them seem to have similar essential features, and to agree with the description given by Aristophanes. In nearly all cases the patient comes to the shrine of Asclepios, sleeps in the "abaton," has a vision or a dream, in which some action is taken by snakes or dogs, or else something similar happens to him while he is awake; and as a result he goes forth whole in the morning. Naturally, cases that are not so cured are not recorded, except in instances where the god showed his divine power by punishing an unworthy worshipper—just as in the Plutus happened to the thief Neoclides.

I now proceed to cite a selection from the cases, without any attempt at classification, in the order in which they are recorded on the slabs.

1. Cleo was with child for five years, and in the fifth she came to the god as suppliant and slept in the abaton; and immediately on leaving it and going outside the precinct, she gave birth to a male child, who directly he was born washed himself with water from the sacred spring and went about with his mother. And Cleo, being thus favoured, inscribed on her dedication: "It is not the size of the picture (or relief) that is wonderful but the divine power, since Cleo was pregnant and bore the burden in her womb for five years, until she slept in the sanctuary and the god made her whole."

This is important as evidence, for Cleo's inscription probably existed, and the rest of the tale may well have been made up to explain it. Possibly Cleo and the child were represented in the picture or relief, and a later generation might not understand the custom in early art of representing young babies as much too mature in form.

2. A man with all his fingers but one paralysed came as a suppliant to the god, and seeing the pictures in the precinct he disbelieved the cures and jeered at the inscriptions. He slept in the abaton and saw a vision. He seemed to be playing knucklebones in the precinct, and the god appeared and seized on his hand and stretched out his fingers. And when he went out he fancied he clenched his hand and stretched out his fingers one by one. And when they were all straightened the god asked him if he still disbelieved. He said no, and the god advised him to distrust his scepticism in future. And when day came, he went out whole.

3. Ambrosia of Athens, with one eye, having come as a suppliant to the god, went round and ridiculed some of the cures, saying it was improbable or impossible that the lame and the blind could be cured merely by seeing a dream. She slept in the abaton, and saw a vision. She thought the god stood by her and said he would cure her, but as his fee she must dedicate in the precinct a silver pig as a reminder of her stupidity. And then he cut open her diseased eye and poured some drug into it; and when day came she went out whole.

Here again we have an indication of the source of the story. The pig was doubtless on show, and the true explanation may be quite different.

4. A dumb boy came as a suppliant for speech, and made the preliminary sacrifice; then the acolyte of the god said, looking at the boy's father "Do you promise within a year, if he gets his wish, to pay the fee?" And the boy suddenly said "I promise." His father was astonished, and bade him repeat it; he did, and was cured from that moment.

This is a case which is, I believe, easily paralleled from modern experience. The next two are evidently edited with a purpose. I summarise them briefly:—

5. Pandaros had certain spots on his forehead. The god appeared to him in a dream, and put a bandage on them, bidding him on leaving to dedicate the bandage. When day came he took off the bandage and dedicated it in the temple, and his spots were gone. Echedorus, who suffered from the same complaint, came with a sum of money from Pandaros to dedicate to the god. He saw a vision in a dream. He thought the god asked him about this money, and he denied it, but promised to dedicate a picture if he were cured. The god put Pandaros' bandage on his forehead, and bade him when he went out to wash his face from the sacred spring, and look in the water. He did so, and saw that Pandaros' spots were added to his own previous ones.

6. This case is of a boy suffering from stone. He thought the god stood by him and said: "What will you give me if I cure you?" and he said "Ten knucklebones." The god smiled and said he would cure him; and when it was day he went out whole.

7. A man came to the god as a suppliant so blind in one eye that only the empty socket was left; some pointed out his folly in thinking he could come to see when there was no eye there. He slept and saw a vision; he thought the god mixed a salve and opened his eyelids and poured it in; and when day came he went out seeing with both eyes.

Here a comparatively common case seems to have been improved by the priests to increase the wonder of the cure. The next is a quaint story, not medical at all, but apparently intended to show the general powers of the god.

8. A porter fell down more than a mile from the precinct, and found some vases in his satchel were broken, including a cup his master used to drink from. He was distressed and sat down trying to piece together the fragments. A stranger passing by said, "That is no use, not even Asclepios could make that cup whole." He went on to the precinct, and when he opened his satchel he found the cup whole. He told the tale to his master, who dedicated the cup to the god.

I fear I can offer no explanation of this story, which shows we must admit some items to be pure invention. But doubtless the dedicated cup was on view to convince sceptics. Another case shows a human touch which reminds us of an incident in the Acts of the Apostles.

9. Æschines, when the patients were sleeping in the abaton, climbed a tree to look into it. He fell, and struck his eyes on some stakes. He was blinded, but he became a suppliant to the god, slept in the abaton and was made whole.

The next case looks like a simple example of surgery, possibly improved in detail, especially as to the quickness of recovery.

10. Euhippus carried a spear-head in his jaw six years. While he slept in the abaton the god took out the spear-head and placed it in his hands. And when day came he went out whole with the spear-head in his hands.

11. A man of Torone suffering from leeches slept in the abaton and saw a vision. He thought the god cut open his chest with a knife, took out the leeches and placed them in his hand, and sewed up his chest again. And when day came he went forth with the creatures in his hand and was made whole. He had swallowed them in a potion given him craftily by his step-mother.

12. Hermodikos was paralysed. When he slept in the abaton the god cured him and bade him when he went out to carry the biggest stone he could into the precinct, and he brought the stone that now lies in front of the abaton.

Here again the visible stone may have suggested the story.

13. Nikanor, a lame man, was seated; and a boy while he was awake stole his staff and ran away. He jumped up and pursued the boy, and from that time he was cured.

14. A man had his toe healed by a snake. Suffering greatly in his toe from a malignant wound, he was brought in the daytime by his attendants and sat down on a bench. He fell asleep, and a snake coming out of the abaton cured his toe with its tongue, and then went back into the abaton. When he awoke and found himself well he said he had seen a vision. He thought a beautiful youth applied some medicine to his toe.

This last reminds us of the cure of Plutus in Aristophanes; it is also interesting from the curious correlation of the vision in a dream with what actually happened; a confusion of the two may explain other cases. A belief in the healing power of the snake is of course common enough.

15. Alcetas, being blind, saw in a dream the god approach him and open his eyes with his fingers, and he saw the trees in the precinct. And when it was day he went forth whole.

This curiously reminds one of the blind man in the Bible, who saw "Men as trees walking."

16. Heræus had no hair on his head and a bushy beard; ashamed of being a laughing-stock to others he slept in the abaton and the god anointed his head with a preparation that made his hair grow.

It is to be noted it is not stated in this case that the cure was instantaneous.

17. Thyson, a blind boy, was licked on the eyes while awake by one of the dogs in the precinct, and went forth whole.

Here there is no vision or dream, as in the case of the man cured by a snake. Dogs also are commonly reputed to have this healing power, possibly because they lick their own wounds. Sacred dogs and snakes were evidently kept in the precinct for the purpose.

I have given a practically complete version of this inscription because I think the form and details of the cures quoted are of importance in forming any just estimate of the value of the record. The other slab is not so well preserved, and the records of many of the cases are only fragmentary. I do not therefore propose to reproduce them in detail; in general character they are similar to those on the first slab. But two or three of the cases are of a special interest, and I add them in summary form.

18. The mother of a girl at Sparta consulted the god on behalf of her dropsical daughter. She dreamt that the god cut off her daughter's head and hung her body neck down; when much liquid ran out, he sewed the head on again. She returned to Sparta and found her daughter, who had had the same dream, restored to health.

This kind of vicarious incubation is unusual.

19. A somewhat similar case is that of Aristagora who had a worm in her intestines. She slept in the shrine of Asclepios at Troezen, and had a dream. She thought the sons of the god, who was himself away at Epidaurus, cut off her head, and being unable to replace it, sent for the god. Meanwhile day came, and the priest saw the head separate from the body. The following night she had again a dream that the god came and replaced her head, and then cut open her abdomen, removed the worm, and sewed her up again.

Here there is obvious confusion between dream and reality, and the priest, seeing head and body apart, seems to be a corroborative detail. But the chief interest in this case lies in the fact that the same story, with some variation, is told by a writer some two centuries earlier than the inscriptions, Hippys of Rhegium. According to his version, the lady came to the precinct of Asclepios at Epidaurus, not the one at Troezen; the temple attendants attempted the cure, cut off her head, removed a gigantic worm, and then could not put the head on again. The god came and blamed them for their presumption, and put things right. It is evident that the priests would not tolerate a record of such blundering in their own temple. One or two other cases have features of interest.

20. A man having what is described as a wound or sore in his belly was lashed down when he resisted operation. Asclepios cut open his abdomen, removed the sore, and sewed him up again. He was cured, and the floor in the abaton was covered with blood.

21. A man suffering from headaches dreamt that the god gave him some training for the pancration; he was cured, and soon after won the pancration at the Nemean games.

22. Finally, a lady suffering from indigestion dreamt that the god gave her some medicine in a cup to drink which made her sick, so as to fill her basin. And when day came there was her basin full of vomit, and she was cured.

In this last case the dream seems to correspond with the fact.

These inscriptions have been much discussed, and some think them a mere tissue of superstitions and absurdities. But so high an authority as the late Sir Clifford Allbutt says that—

> "by pomp, splendour, and ancient enchantments the senses were captured, and the springs of nervous energy unsealed. . . . It is supposed that mesmerism was a potent means in the hands of the priesthood; that patients were subjected to hypnotic suggestion we know with some fulness."

I am not, of course, competent to criticise the evidence from a medical point of view, but I have studied both the records and the psychology of the ancient Greeks, and I think that, allowing for some improvement in editing on the part of the priests, above all of some confusion of dreams and facts, many of the cases above may be attributed either to medical or surgical skill, and that among them are also cases of faith-healing or of sudden impulse or suggestion due to nervous excitement. However this may be, the priests of Asclepios certainly changed their practices in later times, and seem to have taken to running sanatoria and no longer depending on instantaneous cures, for which faith no longer was forthcoming. A good example of this later treatment is offered by the case of M. Julius Apelles, in the second century A.D., who suffered from chronic dyspepsia, and was ordered by the god to take a kind of rest cure, with prescribed diet and regular exercise. Such prescriptions are not uncommon, and show that the various shrines of Asclepios had become centres of medical and even surgical therapeutics.

INCUBATION SHRINES.

Asclepios was not the only god or hero in whose shrines the custom of incubation was prevalent. In the precinct of Amphiaraus at Oropus it was customary for invalids who consulted what was practically a dream oracle to cast gold and silver coins into the sacred spring. They sacrificed a ram, and slept on its skin in the temple or a portico attached to it; they then related their dreams to the priests, who gave expert interpretations. We have unfortunately no information as to what these were like, but they may have given opportunity for medical advice. The shrine was a popular one, and therefore must have met with some success.

In another shrine, that of Trophonius at Lebadea, there were elaborate arrangements which seem to imply some mechanical devices and trickery. The traveller Pausanias, who himself went through the process, gives an elaborate description of it. After some days of preparation, with sacrifices, special diet, and cold baths, on the night chosen the patient was bathed in the river, led to the two springs of Forgetfulness and Memory, of which he had to drink, and then he descended by a ladder into an artificially constructed hole in the ground. Here he lay down with his feet up to the knees in a hole at the side. His whole body was immediately drawn through the hole by an irresistible force; the oracular response was either by sight or hearing, and he returned again through the hole feet first. The priests took him, placed him on the seat of Memory, and interrogated him as to what he had seen or heard, and then returned him to his friends, in a state of terror and unconscious of his surroundings. But he soon recovered and laughter returned to him. The priests, here also, gave expert interpretations of the sounds or visions. The oracle was mostly, though not exclusively, consulted by invalids, to whom it must have been a sore trial, though Pausanias declares none of them were ever killed by it, except a soldier who went in hope of loot, and whose body was found some distance away.

Shrines for incubation are by no means extinct in Greek lands at the present day. In conclusion, I should like to describe one of those which I have myself more than once visited. The great church and precinct of the Panagia (Our Lady of the Annunciation) in the island of Tenos is visited at her annual festival by crowds of people from all Greek lands, bringing with them many men and women suffering from all sorts of diseases, especially the blind, the lame, and the paralysed. These are laid, in their beds, on the floor of the church and of the crypt beneath it, which they fill, so that there is barely room to pass along between them. The sight must be very like the abaton in the precinct of Asclepios in old times. The patients are placed here on the eve of the Annunciation, and so spend the night. Every year some two or three so-called miraculous cures take place; one year when I was there a woman who had crawled painfully up to the church with paralysed limbs threw away her crutches and danced back to the harbour amid the rejoicings and congratulations of her friends. I do not think that fraud or collusion plays any considerable part in such cases. It is to be remembered that only two or three out of hundreds are so cured; and those who are not so forget their own state in rejoicing at the healing of another, just as the rest of the patients surrounded Plutus in the play. The many are forgotten, and the few are remembered and recorded. The case of Lourdes is, of course, similar, and I believe nobody now doubts the instances of faith-healing that have occurred there, especially in nervous or hysterical cases. A certain number of such cases, together with some examples of successful surgery or medical treatment, may well form the nucleus around which the sometimes fanciful records of the cures of Asclepios have accumulated.

An Address

ON

THE HUMAN TOUCH IN PROFESSIONAL LIFE.

Delivered to the Students of Guy's Hospital at the Opening of the Winter Session

By MAJOR J. H. BEITH, C.B.E., M.C.
"IAN HAY."

GENTLEMEN,—First of all let me say how greatly honoured I am by your invitation to me to address you this afternoon. My pleasure, however, is somewhat diluted by the fact that I am not in any way qualified to address a medical audience—except to this extent, perhaps, that once, long ago at Cambridge, I took a course of chemistry and physics, as a sort of antidote to a prolonged dose of the classics; and also, because during those far-off undergraduate days my circle of acquaintance lay very largely among gentlemen who kept a human skull on the mantelpiece and a skeleton, or portions thereof, in the cupboard, and whose soaring spirits only drooped—and that for a moment—when their thoughts turned towards a mysterious and awful ordeal which lay waiting for them about the end of their third year, called the Second Part of the Second M.B. Moreover, it was in that noble company that I first made the acquaintance of my friend—your friend—our friend—Dr. H. C. Cameron, through whose offices, good or bad, I find myself here this afternoon.

We were a band of brothers in those days, with all things in common. Some of us were studying classics, some mathematics, some theology, some medicine, and some, of course, were merely hoping to be excused the General, or be allowed an ægrotat in botany; but just as you can distinguish the voice of the saxophone above all the other instruments in a jazz band, so medical interests and medical shop overtopped everything else. If one of our medical friends performed the feat of "passing his bones," we celebrated the event together, theological students and all. I became well versed in the airy chatter and gossip of what were called in those days, and I suppose are still called, the meat shops; and I shall never forget the scene of enthusiasm which occurred one evening, the first evening of term, when an excited second year man—one of those busy persons who are always full of what we will call, not inappropriately, inside stuff—burst into my room, where I was entertaining a few medical friends, seized Cameron by the hand, shook it warmly, and said to him: "Congratulations, old man! You've got a head and neck!" It is upon such slender foundations as these that I am endeavouring to build up sufficient courage to address you this afternoon.

PERSONALITY AND TRAINING.

I have labelled my discourse the Human Touch in Professional Life, by which I mean character, or personality, as compared with technical knowledge and ability. Of course, the one must not be regarded as a substitute for the other. No force of character, no attractiveness of personality in the world, can ever compensate for ignorance of one's job—in your profession of all professions. Personality is a useful, and sometimes invaluable, appendage to a man's professional equipment, but it can never constitute an equipment in itself.

I emphasise this rather patent fact because there is a general and dangerous tendency in the world to-day to exploit this personality stunt to an absurd degree, to the neglect and detriment of real training and thorough knowledge. In other words, we live in an age of advertisement—in an age, that is, where people are tending more and more to expend their energies, not upon putting quality into their goods, but upon thinking out ingenious and profitable methods of disposing of those goods. The theory appears to be that if you advertise them long enough and loud enough it does not matter whether your goods are good or not. So the art of advertising has now been elevated to one of the high and solemn mysteries. There are actually colleges and institutions in the world to-day at which you can receive instruction, and win diplomas, in this art—the art of ascribing to an article virtues which it does not possess so persistently and so convincingly that ultimately you succeed in unloading it upon someone who does not want it. I speak with some feeling in the matter, because I myself am the possessor of, I think, 28 volumes, in half-morocco, of an obsolete encyclopædia which I was recently dragooned into buying, on the instalment system, by those exact methods.

From this you will realise that the whole aim of modern advertising, whether you are selling encyclopædias or merely trying to get elected to Parliament, is to delude your hearers into confusing promise with performance; and the odd part about it is that the advertiser often ends by deluding himself. For instance, upon the premises of our most progressive railway companies you may possibly have observed pictorial posters depicting an express train, in three colours, dashing along a highly burnished permanent way at 70 miles an hour, supported by alliterative captions on the subject of Sunny Southern Sunshine Specials, or something of that kind. The railway companies in question obviously regard that poster as a perfectly adequate substitute for an efficient train service; and what is more, they can hypnotise some of their passengers into agreeing with them. We succumb to political wiles in the same fashion. One politician gets up and promises us that he will take a shilling off the income-tax. A second gets up and promises to make it two shillings; and so fascinated are we by the glamour of advertisement that we promptly vote for the second candidate, although we know perfectly well that neither of them has the slightest intention of taking anything off the income-tax at all.

So you see, if you want to get on in this world quickly you must advertise. And if you want to advertise successfully, the best way is to get into personal contact with your victim; and, of course, in personal contact it is your bearing and your manner which will count. Therefore, to be a successful man of business nowadays you must have personal magnetism or charm; and if you have not got charm you must acquire it—in other words, you must apply to persons who can sell it to you. And there are such persons. The other day I came across a most invaluable book, obviously of American origin, in which was set forth the whole art of making yourself attractive, and even lovable, to people to whom you want to sell something. In anticipation of my next interview with my publisher, somewhat overdue, I studied this little volume very carefully.

Personal Questions.

It started with a sort of examination paper, in which you were asked 40 questions about yourself, which you had to answer honestly and to the best of your ability, and then allot yourself marks for each. Here are a few. I pass them on to you, because I feel that it is not fair to keep such pearls to myself:—

1. Do you wear colours that are best suited to your type? If so, credit yourself with five marks.
2. Do you start to work every morning with clean finger-nails, clean boots, shaved, trousers pressed, suit and linen spotless? If so, credit yourself with five marks.
3. Can you walk across a room full of guests, speak to the hostess, and conduct yourself without awkwardness or embarrassment? If so, credit yourself with five marks.
4. Do you gesture from your shoulders instead of from your elbows? (See p. 135.)

Being entirely baffled by this question, I turned to p. 135, and discovered that to make gestures with your elbows is wrong, because if you do, "you do not include all the persons in a room." I had never known that. Anyhow, not knowing which part of my anatomy I do gesture with, I gave myself no marks and passed on.

5. Do you avoid using cheap, boastful expressions ? Are you making some effort to improve your vocabulary ? Do you own a good dictionary ? If so, credit yourself with five marks.

I did not quite grasp the connexion between these questions, but I gave myself three marks. After all, I do own a dictionary.

6. Do you give a certain amount of thought in advance to your conversation with people you know you are to meet, so that you will be sure to talk of things that are of interest to them ? (See Chapter 7.)

I looked up Chapter 7. It said :—

Here are some general questions with which to open a business conversation. Others, equally interesting, will occur to you.

(*a*) How far back can you remember ?

(*b*) Do you fear death ?

(*c*) How is your wireless working ?

(*d*) How far do you consider you are indebted to your parents for all they have done for you ?

(*e*) Do you think doctors should charge their patients in proportion to their incomes, or should they have a standard fee for their services ?

I did not think that any of these topics would really interest my publisher, so I abandoned that chapter, and passed on to the seventh question.

7. Do you avoid making a public display of your affection for your wife or sweetheart ?

I unhesitatingly credited myself with five more marks, and closed the book. There were 33 more questions, all as good as that, but I need not trouble you with further extracts. However, I think I have made it sufficiently clear to you what a complicated job it is in these days to fit yourself to be a really successful and lovable salesman.

THE ART OF HANDLING PATIENTS.

Still, at the back of all this rather fantastic stuff there is a real strain of common sense. Of course, it is of importance—enormous importance—to be able, on the top of all your intrinsic and technical merits, to suit yourself to your company and employ your natural gifts to their best advantage. And in the cultivation of the healing art—your art—I think you will admit that the human touch is of incalculable importance. I suppose it is true to say that as much healing is produced by suggestion as by physic, and that many a patient gets well simply because he believes in his doctor. We need not go all the way with Samuel Butler, who tells a story somewhere of a man who swallowed a doctor's prescription in the belief that it was actual medicine, and was immediately cured of a dangerous illness, but the human touch does count, all the time. A doctor is above all things a propagandist. To a certain extent he is always playing a part—backing up the resources of science by the arts of the skilled advocate ; mixing the powder and the jam in such proportion that the powder escapes notice yet achieves its purpose ; doing everything, in fact, that is morally justifiable to create, maintain, and increase the confidence of the patient in his own chances of speedy recovery.

This brings us to the real heart of our subject—the consideration of the gentle art of handling patients. I can say something about this, because, although I have never been a doctor, I have occasionally been a patient ; and I agree with you, right away, that patients are a most unreasonable tribe of people. You can divide them into many classes, but three will suffice here :—

1. People who are really ill. We need say no more about these, because they give little or no trouble.

2. Patients who are rather ill, but do not believe in doctors, and tell you so quite frankly. You know the man who says to his doctor :—

“ I only called you in because my wife insisted on it. I know as well as you do that the whole medical business is mere mumbo-jumbo, mere quackery ; so don't start taking my blood pressure or doing any conjuring tricks with thermometers and stop-watches. I know how my inside works much better than you do, because it's my inside and not yours. You can leave me some medicine if you like, just to save your face ; but I warn you I shall throw it out of the window.”

That's the bluff, honest, hearty type of patient, the type that has made the name of Englishmen respected all over the world.

Well, the simplest and most profitable way to handle this individual is to employ the soft answer. You say :—

“ My dear fellow, I agree with every word you utter. Of course, you are quite right ; all medicine is nine parts faith and one part colouring matter. You and I both know that, so there is not the slightest use in my prescribing for you in the ordinary way. If I may say so, it is a treat to encounter a patient with whom a doctor can be absolutely frank—a patient who doesn't want things wrapped up in meaningless phrases. You, as of course you probably know without my telling you, are suffering from ——.”

Here you give him the name of his disease in Latin —two longish words, with a false concord thrown in. You add a few scientific terms about reflexes and secretions, and so on, and wind up, if possible, with an incorrect chemical formula. After that, he will simply eat out of your hand. Technical terms are the medicine he wants. Many a man will positively enjoy a tennis elbow if he is allowed, when he talks about it at the club, to refer to it as “ my synovitis.”

Then we come to a third class of patient—the patient who thinks he is going to die forthwith, if not sooner, and has to be cheered up. In that connexion I cannot resist calling, or recalling, to your notice one of W. W. Jacobs's stories about that immortal trio Sam, Peter Russet, and Ginger Dick. I want to read you an extract. Sam, you may remember, was taken ill.

“ And,” continues the Night Watchman, who tells the story, “ like most 'ealthy men who get a little something the matter with 'em, 'e made sure 'e was dying. 'E sent Peter out for a doctor, and in about 'arf an hour Peter came back with a sandy-'aired young man with red eyelids and a black bag. ‘ Am I dying, sir ? ’ ses Sam, after the doctor had listened to his lungs and 'is 'art, and prodded 'im all over. ‘ We're all dying,’ ses the doctor, ‘ only some of us 'll go sooner than others.’ Peter and Ginger Dick took turns to be with Sam that morning, but in the arternoon the landlady's mother, an old lady who was almost as fat as Sam 'imself, came up to look arter 'im a bit. She sat on a chair by the side of 'is bed and tried to amuse 'im by telling 'im of all the death-beds she'd been at, and partikler of one man, the living image of Sam, who passed away in his sleep. It was past 10 o'clock when Peter and Ginger came 'ome, but they found poor Sam still awake and sitting up in bed propping 'is eyes open with 'is finger.”

Well, that's a good example of how not to do it. What a patient of that kind wants is to be reassured ; and that is where technical knowledge will not avail you so much as a cheerful presence and a confident manner. And here, speaking from my experience as a patient, may I drop a hint to future G.P.'s ? Humanity fears one thing above all others—the unknown. What frightens a patient most of all is to have nothing definitely wrong with him. Once a definite cause has been assigned to his ailment, once you have hung a label on it marked in plain figures, and given him something physical to hold on to, he will endure almost anything. So if you can, be explicit with him upon this point, even though you may not have the slightest idea what is the matter with him. Tell him something—anything that will keep his imagination from soaring into the regions of unhealthy speculation. Anything will do : a man is never frightened of a thing he knows all about, or thinks he does. It is a good plan sometimes to be symbolic—to illustrate the patient's condition, or supposed condition, by some mechanical analogy. You can refer to trouble in his engine-room, or explain that his dynamo requires tuning up, or his accumulators recharging, or that an overstrained spring must be relaxed. Something tangible and concrete like that—something he can bite on. Tell him that he has a Rolls-Royce body, but that there is water in the carburettor, or the petrol pressure is faulty. That will cheer him up much more than to tell him baldly that his malady is functional and not organic. It is a strange thing, the amount of solid comfort a nervous person can derive from having his interior compared to that of a motor-car; but the comfort is there—especially if you tell him he's a Rolls-Royce.

THE SENSE OF RESPONSIBILITY.

Now, gentlemen, you must not think, because I am referring lightly at times to your responsibilities, that I do not realise very thoroughly how great and solemn those responsibilities will be. Yours, I suppose, is, with the possible exception of the teaching profession, the most responsible profession in the world. And for that reason you may be proud and thankful that you spring from the race you do, because our race possesses in a peculiar degree a quality which is indispensable to men of your calling—initiative; ability to act without running to someone else for instructions; readiness to assume responsibility as a mere matter of course. An Englishman possesses an extraordinary capacity for reliable work in a subordinate position, or perhaps I should say capacity to perform a task efficiently and conscientiously without any sort of supervision from higher up. Who are the men who keep the wheels of our Empire running? You may safely say they are not the people at the top. As a nation, we have seldom been well led or wisely directed in all our history. The main strength of our country lies, and always has lain, in our men-at-arms—our Other Ranks, as they call them in the army—whether those ranks be military or industrial, or administrative, or professional. Most of our successes, whether in war or peace, have been what we are proud to call soldiers' battles—the victories of the average man—the average Englishman. He is not brilliant, he is not spectacular, but you can rely on him. In South America they have a phrase, *Palabra Inglesa*—"on the word of an Englishman," and it means, with them, "Honour Bright!" That is the most splendid compliment ever paid by one nation to another, and it is addressed in the main to the man whom we are considering now. We ourselves depend on him to such an extent that we pay him the compliment of taking him as a matter of course—and we are seldom disappointed. The Civil servant, the platoon commander, the head clerk, the junior form master, the slum curate, the country doctor—these are they that propel the ship of State. Up above upon the quarter-deck, looking portentously wise and occasionally quarrelling for the possession of the helm, you may behold their superiors; but these friends of ours remain below the water-line—unheeded, uncredited, and to a large extent unsupervised, and that is the main point—and see to it that the wheels go round. They grumble and grouse, of course, and tell one another they are fed up—and usually they are—but they carry on, because initiative and responsibility are in their blood. They expect no thanks, and they are not disappointed. But the ship goes forward, and that is all they care about. Win or lose, sink or swim, in good times or in bad, that is what counts—the ship, the cause, the job, and not themselves.

Our Empire, like most of our institutions, came into existence in the most casual fashion. It was never acquired officially; it was never built up upon the ambitions or intrigues of kings and ministers. It was founded upon the efforts and sacrifices of common men—men whose very names have perished—who went out from our little island because the spirit of adventure bade them go out and better themselves, and who planted the seeds of enterprise and justice all over the world, to the complete effacement of themselves, and too often at the sacrifice of their own lives—men, in other words, who set the cause above the prize. It was only when through their efforts our interests in this quarter of the globe, or that, grew too unwieldy or important for private control that the British Government, with a deep sigh and an anxious eye on the taxpayer at home, reached out a reluctant hand and took official command.

To-day, all over the world wherever our flag flies, men you never heard of, and never will hear of, are shouldering responsibilities, making rapid decisions, improvising working expedients, getting the wheels round somehow—not for any special honour or glory that is going to accrue to them, but because it is their job, and it is up to them and them alone to do it. So they do it, by sheer force of character, personality, and the human touch. These are the things which bring them through. And foremost among those men I salute the members of your profession, because that profession bears as heavy and as proud a share of those burdens and those responsibilities as any.

THE FUTURE OF THE MEDICAL STUDENT.

Now I think I have said all I intended to say—or something like it—and it only remains for me to wish you good luck in the career that you have chosen. Many branches of that career are open to you, and no one of you knows exactly what the future holds in store for him. It may ultimately land you in Harley-street or at the head of some great hospital. It may make you a student of research, devoting your life to the study of a single disease or the isolation of a single germ. It may send you overseas as a medical soldier or a sailor, or as a member of some scientific expedition to a far tropical country. Or it may simply plant you down as a general practitioner in a manufacturing town, working 18 hours out of 24, with a large, troublesome, and for the most part unremunerative family of patients running to you all day long to have their hurts healed or their fears allayed. But wherever fate may place you, however high or low; however hard you may have to work; whatever difficulties and discouragements you may encounter—and you may be sure they will come—nothing can take away from you the sheer greatness of your chosen profession. Yours is one of the few essential trades on earth; it goes right down to the roots of human existence. You are the standing army and navy of humanity. Your life is one long campaign on behalf of other people, against ignorance, and dirt, and cruelty, and disease. We can never do without you. You bring us into the world; you attend us upon our voyage through life; at any moment we may call upon you to dry-dock us, or more frequently assist us to carry out that most ticklish of undertakings, the execution of repairs while under steam. And when the time comes for us to pass beyond the horizon of human life, we call upon you again, for the last time, to assuage our sufferings and soften the pangs of death.

You see, we depend upon you in all things; and we trust you implicitly. To your hands we commit the innocence of our children and the honour of our womanhood; and it is the special glory of your profession that these commitments are made without question, as the merest matter of course, because we know that they will never be abused. For generations that tradition has been passed down, and it is to that tradition and heritage that you are now about to succeed. Here in Guy's Hospital you have a great history and a wonderful record. You were at work 200 years ago, and to-day your activities are greater than ever. Only a few years ago Guy's men were doing their duty on every fighting front in the war, and Guy's nurses too. I well remember at the Battle of Loos, almost ten years ago to-day, a specially constructed communication trench for stretcher-cases only, which was called "Guy's Avenue." And you have a proud reputation here for team-work and esprit de corps, whether in your work or in your play, as those who have encountered the Guy's Football Fifteen have cause to remember. Altogether, a great tradition and a great heritage. So I say, go on and prosper!

And one last reminder on the matter of my text. You will note that I have heroically refrained throughout this rambling discourse from urging you to cultivate what is known as an "agreeable bedside manner." I still refrain, but let me remind you once more that a few words of cheery common sense and unprofessional informality will often do more for the average patient than the whole British Pharmacopœia. So, steep yourselves as deeply as you like in the knowledge and lore of your craft, but do not forget the Human Touch!

An Address
ON
THE STUDENT-HABIT.

Delivered at the Opening of the Winter Session at King's College Hospital

By Sir ARTHUR KEITH, M.D. Aberd.,
HUNTERIAN PROFESSOR, ROYAL COLL. OF SURGEONS OF ENGLAND.

Of all the men it has been my fortune to meet in the flesh, Clifford Allbutt, Regius Professor of Medicine in the University of Cambridge, came nearest to my ideal of the real student and the perfect gentleman. He died in February of the present year, having reached his eighty-ninth year. For 70 of those years he was a professed student, and yet at the end of his term he carried his load of learning with ease and comfort as if it were a garment which had become part of him. He never suffered, so far as one can learn, from that fell disease which so often wrecks the lives of budding students, mental dyspepsia. For his brain managed its affairs as a good woman runs her household; every article admitted to his mind had first to be sampled; when admitted the right place was found for it; every article admitted had to add to the efficiency and comfort of his mental household; every room had to be furnished and used. And yet at the end of a lifetime of toil—a toil which had been his constant pleasure—he still continued to make additions and alterations to his mental furniture. His mental household, like that of a thoughtful, happy, generous housewife, prospered in that which it gave away. The giving away kept the rooms of his mind sweet and living.

I have cited the example of Clifford Allbutt in order that I may make clear to you what I mean by the "student-habit." He could sit down by the hour and apply himself with a sense of pleasure to gleaning knowledge from the written or printed page, drinking in and assimilating facts observed or explanations given by men who had toiled in years long gone by. He applied himself with equal ease to the writings of his contemporaries, men who were still toiling in their laboratories or in their wards. The men or women who can acquit themselves thus have acquired the student-habit. Of all the struggles men undertake, that which ends in making the brain the willing slave of study is the most arduous. Of all mental habits it is the one most difficult to come by, and the one which is most easily lost.

Many men who are masters of research, who force secrets from Nature by experiment, who prefer to glean their knowledge at first hand and are, I admit, the rarest and highest form of scholars, often despise the habit I wish to extol—the student-habit. There have been, and there are, successful medical men who turn aside from books, who leave their medical papers unopened in their wrappers, who prefer to be guided in thought and action by what their fingers have felt and their eyes seen. If by neglecting the student-habit they gain something, they also lose much, and it would go ill with their harvest of knowledge if their successors treated them in the same selfish way as they have done their predecessors. I do not claim for my ideal student, Clifford Allbutt, that he was a pioneer who opened up great new fields of knowledge, but he attains to my ideal because he checked what he saw and what he suspected against the observations and the theories of the great minds which have paved the highways of medicine. Nature had endowed him richly, but he could never have done what he did nor been what he was unless he had acquired the student-habit. I speak as an old student of ordinary ability, to young students born into the same happy estate, and I say that the acquisition of the student-habit is one of the most valuable assets that a man or woman can carry into any line of life.

At what age Clifford Allbutt acquired the student-habit I do not know, but I can assure you that if it came to him by the age of 20 it had come in due time, for with the best of students the twentieth year is in sight before the real purposes of life dawn on their minds. Nor do I know of the struggles which he went through before the habit of study became his second nature—such biographical details are usually overlooked—but I am certain that, even in his case, there had been a struggle, for of all human habits that of the student is the most unnatural and the most forced; it is a hot-house plant which can thrive only when enclosed in the glass houses of the highest civilisations.

Our Illiterate Forbears.

The student-habit is comparatively new amongst the peoples of North-Western Europe. A thousand years ago our British forbears, although rich in the knowledge of life, were in the full meaning of the term illiterate; for many thousands of years their forefathers had been hunters, fishers, crofters, and livers in the open air, drinking in traditional knowledge by word of mouth. The peoples of Western Europe produce the highest form of students the world now has, and yet the student-habit is for them a recent importation. It was otherwise in the East; 6000 years ago, perhaps 8000 years ago, young men in Babylonia and Egypt were acquiring the student-habit; it began as soon as the human mind conceived that knowledge could be inscribed on stone or brick; with that discovery was instituted the student-habit. If there is aught of truth in the inheritance of acquired faculties it is from the peoples of the East we should get our finest scholars; they come of long lines of descent in which study has been endemic for countless generations. It is true that amongst the peoples of the East, from Egypt to China, we do often find those who have a marvellous facility to memorise the written or printed page and yet amongst them the Clifford Allbutt type of scholar is rare—almost unknown—the scholar who assimilates what he reads and makes his learning a part of his manhood. Learning thrives in Western Europe just because it has fallen on a strong and virgin soil, one which has not been wasted by the exhausting crops of a long-continued literate civilisation. We have still in us the virility and the energy which are inherent in men and women bred for life in the open air.

It is because you and I have the aptitudes and instincts of our primitive forefathers so strong within us that we find it needs an effort—an internal struggle—to settle ourselves to our books of an evening. Our difficulties are even greater when the sun shines and a longing for the open country stirs our blood; it is then that we have to struggle with the original Adam which is present to a greater or lesser degree in the hearts of all of us. English teachers, beyond those of any other country, have recognised the needs of those primitive faculties which well up in the breasts of scholars young and old; we encourage play and sports of all kinds in our schools and universities in order that the inheritance which has come down to us from savage ancestors may find vent in exercise. Golf is one means of allaying the beast; walking another. It is so difficult for the modern student to weld the needs of our present-day life to his inborn predilections. There are cards, billiards, and theatres ever ready to tempt the unwary student from his stool. For if study is to prosper, is to become a second nature, we have to make sacrifices; dances, festivities, and pleasant company have to be kept within the bounds of moderation. To dance, to sing or play, to feast, to gossip are the outlets of the natural man; ever since our distant ancestors emerged from the jungle these instinctive outlets for enjoyment have been clung to and cultivated; they have come down to us in an undiminished vigour. Before the student-habit can be acquired they have to be—not vanquished or eliminated—but disciplined. That is why it is so difficult to become a real student.

Reaction of Brain and Stomach.

You will not be a student for many years before the most natural of all human appetites begins to give you concern. Amongst the prerogatives of life we count the enjoyment of food; we expect to eat with relish and to enjoy the results of repletion. We are not quite certain what our brain cells live on, but we do know that they need very little to do the heaviest work we throw on them; the energy in an ounce of sugar would be enough, I suspect, to produce any of Shakespeare's plays, if it found its way to a brain gifted as his was. Everyone of us has been given the appetite, not of the brain-worker, but of the muscle-user. The professional student, in his earlier years, expects to satisfy his appetite just as fully as if he were using his muscles all day in the open air, and sooner or later his stomach has to pay the price of his acquired habit of study. Carlyle, Darwin, Huxley, and Herbert Spencer suffered from this "student's disease"; it is true all were moderate eaters and yet their stomachs were in a state of continual upset and rebellion, yet they all lived to a ripe age. Modern physiology has given the stomach a secondary place in the hierarchy of bodily organs. And yet somehow, as students know to their cost, sooner or later, brain and stomach react furiously upon each other. It is true that we do come across eminent students who have the physique, complexion, and appetite of yeomen. They are exceptions and should count themselves fortunate. Most of us who take to habitual study have to pay the price and the more we give our stomachs to do the higher is the price we have to pay. To become a real student you have to be prepared to make sacrifices. For your encouragement I would say this, that I know of no student who would exchange a regulated brain for the healthy appetite of the mental sluggard.

Many of us, perhaps most of us, have grown up under the belief that it is a natural thing for young men and women to give themselves to study. It is only when we approach the problem of the acquisition of the student-habit from the long-range historical point of view that we see how foreign the habit is to our nature and how recently the need for it has arisen. Some can claim that their family has produced scholars, learned men and women, for many generations; such are the exception rather than the rule. The majority of eminent scholars have no scholarly lineage. They come from highland glens, Welsh hillsides, English county villages, the first of their kind, so far as they can tell, who ever devoted their lives to the cause of learning. There must be throughout the length and breadth of our land immense and virgin fields of untapped scholarly talent. I am not speaking now of those rarely gifted minds which can imagine things which are new and true, which know the way to make Nature yield up her deepest secrets or discover how to harness new forms of energy for man's benefit, but of the rank and file which make up the learned army of a country. To join that army every recruit must learn the student step—the habit of study. It may at first sight seem surprising that there should be such an abundance of potential students in a population of manual labourers. But when one looks into the quality, which is needed above all others to make a man a master-student, it is no longer surprising, for we see that the essential qualification is a power of steady application in any line of endeavour whatsoever. The potential student must have method and foresight as well.

Brains Ancient and Modern.

When the modern student compares his outfit of brain with that which was given to his ancestor in remote times he meets with another surprise. The men who lived in Europe 20,000 years ago were just as well equipped as he is as far as concerns size and form of brain. What did those ancient hunters do with so big a brain? They had no professional examinations to pass, no briefs to master, no leaders to write, no mathematical problems to solve, no ancient classic to translate, no sermons to prepare and preach. If brains were given to us merely for such purposes then those ancient hunters had somehow come by a superfluity. Brains, however, serve the needs of much more than the intellectual side of our lives; beneath the intellectual centres lie a myriad of others which subserve more menial duties—by the exercise of which we fill the cup of life's enjoyment. But even this explanation is but partial; the full explanation lies much deeper and has to be sought in a strange law which regulates the construction of all living structures. All such structures have been framed on the rule which provides a large margin or factor of safety. All our organs—our hearts, our lungs, our stomachs, and our brains—have been built to meet not the daily routine of life, but emergencies which occur only at critical junctures. The heart on an occasion can rise to ten times its usual output; the lungs, if pressed, can nearly do as well. As for the stomach, the less said the better; modern civilisation tends to throw an unfair burden on it. But as for the brain, the factor of safety law holds good; we have, and our ancestors had, about ten times more than ordinary occasions require; our superfluity was given us for emergency. It is just this emergency ration that the modern scholar has to depend on, and there are few, if any of us, who use this extra allowance to its full capacity. You may study to the utmost limit of your endurance, and by the mere act of study you may rest assured that you will do your brain no injury. Infinitely greater harm is done by misuse and disuse of the brain than by overuse.

Let me make certain that you realise that the brains I am speaking of are not those of children; to push education upon an immature brain is cruelty; I am speaking of the mature brain, the state reached by most of us about the nineteenth year; it is then that the brain cells have come to their complete outfit and connexions. By habitual study you may overtax your physical endurance; you may damage your bodies if you neglect to exercise them, but you certainly will not damage your brain. You will never succeed in using your brain up to its full capacity. At the age of 74 James Watt acquired a knowledge of German, and at 64 Goethe, the German, mastered several Oriental languages. For my own part I use sleep as my barometer; when I begin to find that sleep comes to me with sluggard steps or if there is a tendency for my mind to "race" when I lie down I slack off. There is no greater nonsense talked than that brain-work may bring on "brain-fever."

How to Attain the Student-Habit.

I have been speaking to you about the student-habit—seeking to explain why it is so difficult to acquire, but I have said nothing about how it is to be attained. There is nothing to be said; no one can teach it you; there is no royal and no easy road. Each one has to come by it for himself or herself by self-effort and by self-application. Nor have I said anything about a matter which every student soon discovers. Our brains have moods and tempers; like horses or the engines of motor-cars, they have to "warm up" before they will run smoothly and easily. The start is always the most difficult phase to manage. And often we are uncertain, when our brains start sluggishly, whether pressure will warm them up to study pitch or whether it is wiser to lay science or stiff reading aside and take to fiction. The healing power of a debauch of fiction is often marvellous in its results. The best brains are not like cart-horses which will do a turn at any hour; like race-horses they have their times off and times on. Therein each student is a law unto himself.

If I have been speaking to you who have still examinations to face I have also in mind those happier men and women who have left such ordeals behind them. Sooner or later they will discover that the student-habit, which is gained only by great and continuous effort, is soon and easily lost if not exercised. And they will also discover, as I found to my cost, that it is terribly difficult to get it back again. The medical man or woman who has lost the student-habit has become but a camp-follower in the great professional army to which we should all belong and in the activities of which we should all take a part if medicine is to prosper.

NOTES ON THE SURGICAL TREATMENT OF BRACHIAL BIRTH PALSY.

By JOHN GILMOUR, M.S. Durh., F.R.C.S. Eng.,
HON. ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

The treatment of brachial birth paralysis, especially of the Erb-Duchenne variety, first attracted my attention at the Children's Hospital two years ago. Since then I have had the opportunity of treating several cases and of examining a number of others at the Royal Victoria Infirmary.

After having seen 25 cases of the palsy, one may safely say that the general impression that they mostly recover well, in time, is very misleading. It is said that one only sees the worst cases in hospital, and that there are numbers which do well at home. Up to the present I have not come across any evidence of this. On the contrary, an honorary colleague at the Children's Hospital, who has records of 40 cases, informs me that very incomplete recovery is the rule. Doctors are much more in the habit than formerly of referring their cases to hospital in the early months of the child's life. It is not surprising, therefore, to find that over two-thirds of the number under review did attend for examination and treatment before the end of the third month, most of them in the second month, when the ultimate result was still in doubt or before full recovery might reasonably be expected. Of the 17 who reported early only two can be described as having made a spontaneous recovery, while the others have not shown up much better than the last third who only attended at later dates after domiciliary measures had failed.

Whether it is admitted or not that one is justified in drawing conclusions from these facts, it is evident that there are numbers of children attending hospital with one or both arms crippled from birth for the treatment of which the unaided efforts of the masseur are inadequate.

Varieties.

Of those examined there were 23 of the Erb-Duchenne variety, two of the general arm variety, but none showing a pure Klumpke paralysis. On the obstetrical side all but three of the births were described as long or difficult. In one case the period of labour was short (five to six hours), and in two delivery was natural and unassisted. In the rest chloroform was used to facilitate instrumental or manual delivery. Three infants were said to have been asphyxiated and to have required prolonged resuscitation. The presentation was "vertex" in 16 cases, "breech" in four cases, and irregular in type in five cases. This analysis agrees roughly with that which Stransky made of 94 cases collected from the literature up to 1902. He blames direct pressure or traction upon the plexus in cases of difficult or prolonged labour in which anæsthesia was used, and in which a final rapid delivery was required for asphyxiated infants. Bailey states that overstretching will occur when the head and shoulder are separated more than 120°; and Peter and Bullard add that the stretching is increased by the rotation of the aftercoming part.

Ætiology.

It is not possible here to discuss the ætiology of the condition at any length, but it is worth reporting that in each of the four plexuses which were exposed by operation a definite lesion was found. Of late years a considerable literature has grown up on this subject since T. Turner Thomas propounded the theory that the palsy is only a pseudo-paralysis dependent upon injury of the shoulder-joint produced at birth. Lange supports this view, and Binnie is inclined to credit it; but the weight of evidence of an experimental, operative, and post-mortem nature is all against it, and in favour of overstretching of the plexus as the primary lesion.

Experimental Lesions of the Brachial Plexus.

Fieux, Shoemaker, Prout, Sever, and Adson were all able to produce lesions of the plexus, when exposed in the cadaver, by traction. In the Erb type of paralysis they found that the nerves rupture from above downwards. The importance of the suprascapular nerve which frequently tears first because of its close peripheral attachment was indicated, and the need for its repair stressed because of its control of the external rotator muscles of the arm. Adson states that there is first a laceration of the deep cervical fascia, then of the unsupported epineurium and its vessels, and finally a separation of the nerve-fibres which occurs in the first instance between the ganglion of the fifth cervical root and the upper trunk, and if more force is used results in a partial avulsion of the ganglion itself along with the spinal root. Further strain causes avulsion of the sixth, then seventh cervical roots, and finally laceration of the fascia over the eighth root. He concludes by saying that "Inasmuch as injuries of the plexus are produced in the roots or ganglia, they seem primarily to be lesions of the nerve rather than secondary to lesions of the shoulder-joint. Minor injuries may be expected to recover partly or wholly; severer injuries rarely recover even with surgical treatment."

A. S. Taylor corroborates the impracticability of operating on the intraspinal lesions, although he is a strong advocate of early exploration in the less severe varieties. It is obvious that many degrees of injury occur, and that clinical varieties may be looked for which correspond to the gravity of the lesion. The cases under review illustrate this very well. In age they range from 7 weeks to 15½ years. Several distinct types can be distinguished.

Splint for Type 1. A, Straps to control forearm and hand. B, Strap to control arm. C, Straps to fix to trunk.

Types of Brachial Birth Palsy.

Type 1. The Typical Case.—This is usually seen soon after birth with the characteristic "vertical arm" in which there is paralysis of the deltoid supra- and infra-spinati, teres minor, biceps, brachialis, and supinators. The arm is held in a position of internal rotation, the elbow is fully extended and cannot be flexed, and the wrist is often palmar and ulnar flexed. The arm cannot be abducted actively from the shoulder. Of this variety only three cases were seen, and in two early recovery is taking place. One of these came for treatment when nearly 2 months old, and the history is interesting.

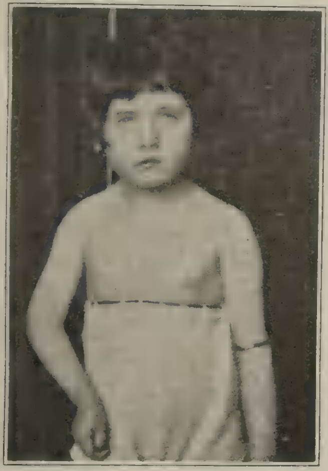
Case 1.—She is a second child, was born by the breech before the doctor came, and had the typical deformity in the right arm. When examined there were distinct signs of movement and a tendency to take up the position characteristic of Type 3 (to be described later). This could be overcome by manipulation easily, but the importance of preventing contractures was realised, and the mother was instructed to move the arm in such a way as to produce: (1) External rotation of the humerus (with elbow at 90°). (2) Forceful abduction of the arm and backward extension of the elbow to push the humeral head forward. (3) Full supination of the forearm and free movement at all the joints. To keep the paralysed muscles at rest a platform splint of thin metal made after A. S. Taylor's pattern (see Fig. 1) was applied, and it was only removed for massage and movements for ten minutes twice a day. Marked improvement in power and in movement had occurred in one month, and during the second the splint was left off for increasing intervals during the day to allow the arm to be exercised. It is worn at nights now until recovery is considered complete. This baby tolerates the splint without a murmur.

If a splint is objected to, the position which it secures of abduction and external rotation of the arm, flexion of the elbow, and supination, can be obtained by fixing the wrist over the top of the head by a strip of gauze passed under the opposite axilla.

The principles involved in this line of treatment are three cardinal ones: (1) Relaxation of paralysed muscles (splint); (2) maintenance of nutrition in these muscles (massage); (3) prevention of contractures (movement). Neglect of the first and third is a sure way to court the onset of complications which transfer the case to Type 3.

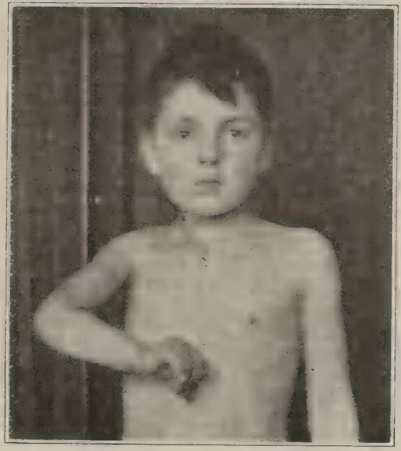
Type 2. The Irritable Type.—This is similar to the first type, but is complicated by an irritable "neuritis" of the plexus, and considerable fretfulness on the part of the infant who, as a result, tends to fix the arm closely to the side and to resist treatment. The prognosis is correspondingly less favourable, and unless adequate measures are adopted it will pass into Type 3. In this series eight of the children were described as irritable, particularly whenever the arm was touched. Six of these passed into the third group, two were subjected to operation on the plexus, and one was seen for the first time a few days ago.

FIG. 2.



Posture of Type 3.

FIG. 3.



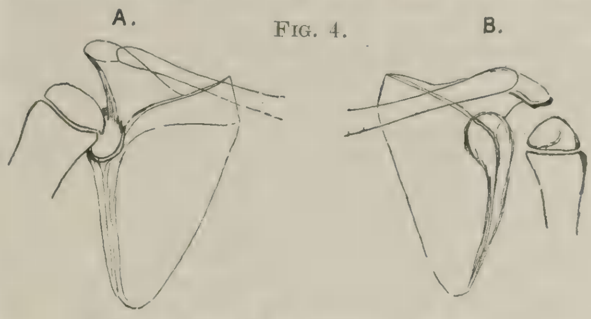
Showing total elevation of right arm.

Early fixation on the splint is therefore most important to relax the irritated muscles and prevent contractures, and to allow the inflammatory reaction in the neck to subside. Gentle massage keeps the weak muscles in tone meanwhile. After two months' rest gradual movement is practised and increased as toleration is established, and then the case is treated as in Type 1.

Type 3. Cases showing Contractures and the Progressive Deformities associated therewith.—These occur where treatment has been inadequate or neglected, and naturally develop only in those in which the lesion is neither too slight nor too great, since in the former recovery is likely to follow, and in the latter none will occur. Fairbank, in a study of 40 cases, found that 60 per cent. showed a definite tendency to muscle recovery, but also that 75 per cent. of them tended to develop contractures. This proportion is not an exaggeration, and it is a strong indication of the importance of proper early management of every case of Erb's paralysis. Seventeen of the cases I have examined have become thus complicated—a proportion of 68 per cent. The characteristic attitude of Type 1 is now replaced by a second posture which is fairly typical in Type 3. In this the arm is held slightly abducted from the side and slightly flexed forward and fully rotated internally; the elbow is flexed about 20° or 30° from full extension and cannot be extended; the forearm is usually fully pronated and cannot be supinated more than 20°; the wrist may or may not be dropped, and the hand retains some of its ulnar adduction. The effect of these contractures on the function of the arm is very crippling. With the elbow fixed at the side, for instance, the hand cannot be carried from the front of the body laterally to the line of the arm because there is no external rotation of the humerus possible. The absence of supination is therefore very marked, and as a result the hand is almost useless.

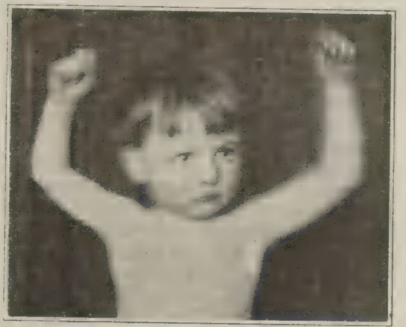
Abduction and forward elevation of the arm are also weak so that the hand, even pronated, cannot be raised to the mouth. Further scapular rotation, assisted by throwing the affected shoulder backwards to raise the ribs in front, adds but little more elevation to the level of the hand. (See Figs. 2 and 3.)

FIG. 4.



A, Normal shoulder. B, Subluxated shoulder.

FIG. 5.



Showing recovery after suture—right arm.

With the absence of functional activity disuse of the limb naturally follows very soon, the contractures become consolidated, vascular changes occur in the extremity of the limb, and an important subluxation is produced in the shoulder-joint. Frequently there is a subluxation of the head of the radius. Growth of the shoulder girdle and of the limb bones is seriously impeded, so much so that the child is apt to lose his balance and often stumbles from this cause.

The subluxation of the shoulder-joint appears after several months. It is easily overlooked in fat infants, but the rounded prominence of the humeral head, behind instead of in front of the tip of the acromion process, is characteristic. The humeral head looks backwards and lies on the postero-inferior margin of the glenoid cavity. It is held there by the strong internal rotation of the contracted subscapularis and pectoralis major, and by the downward and backward traction of the teres muscles.* The lack of support from the paralysed external rotators, the spinati, assists in this displacement and the joint capsule yields accordingly behind, whilst it contracts up in front.

As time elapses bony changes occur which "fix" the subluxation. The glenoid cavity remains small and undeveloped. It may become flat or even convex. The head of the humerus develops into a cone with a flattened side towards the glenoid. It lies at a lower level than normally. The acromion process, and sometimes the coracoid process, becomes bent forwards and downwards—probably from the unsupported weight of the arm, and forms a true bony obstacle to the reduction of the subluxation. (See Fig. 4.)

Radial subluxation is much less frequent, but must be considered due to the combined paralysis of the supinators and the contracting pull of the pronator teres. Contracture of the biceps may also tend to displace the head of the bone forwards and inwards. Turner Thomas described a case in his series of "Neglected Erbs," and was inclined to argue that this was a congenital injury just as he said the subluxation of the shoulders was, but such an explanation is not necessary in the presence of contractures. I have seen the same deformity follow contractures in infantile paralysis. In older children the crippled arm looks particularly small beside the healthy one, which may show a compensatory development. Other interesting features have been observed.

In one case the scapula was drawn up to the humerus by a contraction of the teres major and latissimus dorsi muscles, and this prevented the deltoid from using its full power on the arm, abduction to 50° only being possible. In another case the only residual weakness is in the external rotators of the right arm. This boy complains that he cannot write at school for long without "cramps" near the shoulder, and writes as well with the left as with the right hand. He has an interesting sympathetic paresis which has left him with distinct underdevelopment of the right side of the face, enophthalmos with pseudo-ptosis and a contracted pupil. In this case sympathetic involvement has not had its usual unfavourable significance.

When supination has recovered there is usually only a minor degree of weakness in the shoulder muscles, but contractures and subluxation when present convert this into a much more disabling condition. Recovery takes place from below upwards as a rule, so that in the Erb type of palsy any lingering paralysis in the forearm or hand means a grave prognosis.

The *electrical reactions* of the muscles of this group are not typical when partial recovery has ensued. I have generally found that the posterior fibres of the deltoid, the spinati, and the supinators give a feeble response with faradism and a brisk response with galvanism when the polar reaction may be normal or reversed. Thomas disputes any change in his attempt to substantiate his shoulder-joint theory of origin.

Sensory disturbances have only been found in the whole arm type, and then usually over the ulnar side of the hand and lower forearm. In such cases sensation to "pain" seems to be lost over almost as wide an area as "touch." Sherren has shown that section of the fifth cervical root is not usually accompanied by anæsthesia, and even the sixth cervical may be cut in some cases without any appreciable change in sensation. This, of course, accounts for the absence of disturbance in the Erb type of paralysis.

Operative Treatment.

Expectant measures are only justified in cases where full recovery is anticipated, or when no operative interference is contemplated. Once it is evident that only partial recovery will result, the question of operation should be considered. A. S. Taylor states that recovery should occur, if spontaneous, within three months. Wyeth and Sharpe advocate operation at one month if the lesion remains complete, and at three months if full power is not then regained. In 1903 the late Robert Kennedy, of Glasgow, advocated operation at 3 months of age, and his results are without doubt the most convincing of any. I have never explored the plexus at this early age. The three infants upon whom I operated were $1\frac{1}{2}$, $1\frac{3}{4}$, and $^{11}/_{12}$ years of age respectively, and the fourth was a boy of 9 years. There is no doubt, however, that the longer one waits the more firm is the scar-tissue about the roots of the plexus, and the greater is the actual gap, after a resection, between the nerve ends. At the same time growth changes have occurred which a successful early operation will eliminate. Operation was undertaken when the electrical reactions indicated a nerve block, and in each case was looked upon as an exploratory procedure. In two of the four cases it was possible to proceed further and to resect damaged nerve roots and unite the free ends accurately; but in the other pair it was only possible to dissect adherent and scarred fascia from the front of the plexus.

Clinical Records.

CASE 2.—First child. Male. Very difficult labour. Instrumental delivery with chloroform. Markedly asphyxiated. Vertex presentation. Left arm showed Type 1 paralysis. Attended hospital first when 3 months old. Contractures beginning to form. Splint ordered and worn from fourth month. Massage and electrical treatment given for a year. No improvement of any importance. Electrical reactions taken gave nil response to faradism in deltoid and weak response to faradism in spinati. Operation when 18 months old (8/3/24). External neurolysis. Dense cervical fascia removed exposing only atrophic strands in place of fifth and sixth cervical roots. No repair possible. Latest report on arm shows: General posture of paralysis remains but without contractures. Arm can be elevated forwards to 90°. Elbow flexed to nearly 90° and forearm supinated beyond mid-position. There is still some internal rotation but no subluxation. Child can use hand to steer a scooter.

CASE 3.—Fifth child. Male. "Shoulder presentation." Long labour. Chloroform and manipulation. Right arm shows Type 2 paralysis. First attended hospital when 3 months old. Sent to me by Dr. Glen Davison when 9 months of age. Arm had become Type 3. Splint ordered, with massage and movements. Electrical reactions continued to show no response to faradism in deltoid, spinati, and biceps, and only a feeble response to galvanism in biceps. At this time he could abduct the arm forward to 45°, supinate to mid-position, flex elbow fairly well, but had no external rotation. Operation when $1^{9}/_{12}$ years old (26/4/24). Thick fascia removed. Fibrosed fifth cervical root and twig from fourth cervical found and resected with suture of cut ends. (See Fig. 5.) Latest report is illustrated by accompanying photograph, where it is seen that he can abduct and elevate arm beyond 90°, externally rotate, and supinate.

CASE 4.—Vertex presentation; delayed shoulder. Chloroform and instruments. Asphyxia. Type 2. Irritable. Attended hospital at 1 month. Massage given. Referred to me by Dr. Davison at 11 months with no improvement. Electrical reactions showed nil response to faradism in deltoid, biceps, and brachialis, but biceps and all others reacted to galvanism. Immediate operation (20/9/24). Severe lesion of fifth and sixth spinal roots, with a second tear distal to upper trunk all involved in dense scar tissue. Fifth cervical root atrophic. Tension suture inserted to approximate distal nerves to stump of sixth cervical root. Re-exploration two weeks later to attempt to secure a nerve suture, but this was at once found to be impossible and wound was closed. Latest report: Arm hangs in position of Type 1, and can be moved very little. Sympathetic pupillary change is present in this case, and the prognosis is hopeless.

CASE 5.—Nine years. Male. Thirteenth child. Vertex presentation. Short labour. Both arms paralysed at birth. Right recovered in one month. Left shows clinical picture of Type 3. Contractures and subluxation present. Electrical reactions. To faradism: very weak response in posterior fibres of deltoid, some inactive. Doubtful response in supraspinatus. No response in infraspinatus.

---

* The teres minor has been shown to draw down the humerus and keep the head of the bone in the glenoid cavity when the deltoid comes into action.

Supinators both feeble. Flexors active to galvanism. Brisk response with A.C.C.>K.C.C. in affected muscles. Operation, 5/5/25. Taylor's combined operation on shoulder-joint and plexus. With regard to the plexus a firm area of fibrous tissue was found in an attenuated fifth cervical root. This was resected and suture of nerve ends found possible. It is too early, of course; for results.

In each of the cases the weak arm is raised in a plaster case and fixed with the head inclined towards it to take tension off the sutured nerve ends.

Treatment of Contractures and Subluxation of Shoulder.

It will be seen that in the last case an attempt was made to deal with the complications of contractures and the subluxation. This represents a useful line of attack to improve the function of the limb. Indeed, so great an improvement is said to follow this that Thomas claims to cure the disability and the palsy by so doing.

Most of the patients exhibiting these complications were still below the age of 6, but two were 9 and one 15½ years of age. In the younger patients the bony changes are less marked, but in the older group the subluxation is very prominent, and the acromion and coracoid processes act as bony obstacles to reduction and elevation of the humerus. The manipulative method of Whitman is applicable, therefore, to the younger children, or one or other of the operations described by Fairbank, Sever, Thomas, and Taylor may be utilised in any of the cases.

I have treated three by open operation, in each case combining the division of the pectoralis major and subscapularis insertions (Sever's method) with section of the inner part of the capsule of the joint (as Fairbank suggested), because without it full replacement of the humeral head was found to be impossible. In Case 5 the coracoid process had to be partly removed, and the coraco-humeral ligament divided to allow of full external rotation. The short head of the biceps was, therefore, sutured to the side of the coracobrachialis and pectoralis minor. The after-treatment of these cases is still progressing. Plaster is applied with the arm externally rotated and abducted, the elbow flexed and forearm supinated, and after three weeks a Taylor's splint replaces this so that movements, at first passive, and massage may be practised once a week. When the new joint is consolidated and the muscles have regained control the splint will be discarded. In these cases Taylor now combines exploration of the plexus, and instead of plaster he uses a special head and arm brace for three months.

One small group of cases remains in which complete atrophy of the deltoid and spinati is present. If scapular movement is present arthrodesis of the shoulder-joint will improve the usefulness of the limb. Such a procedure has not yet been tried.

This communication is a preliminary one, and will be followed by a further report on the cases under treatment. My thanks are due to Dr. W. Ogden and Dr. Glen Davison for their cases, and to Dr. George Hall and Mr. H. M. Johnston for the opportunity of examining their cases.

A REPORT UPON NINETY-TWO CASES OF RHEUMATIC DISEASE IN CHILDHOOD.

BY MARTIN O. RAVEN, M.D. OXF.,
M.R.C.P. LOND.,
MEDICAL OFFICER, ST. MARY'S HOME, BROADSTAIRS.

THE Horsfall hospital wards of St. Mary's Home, Broadstairs, have, since 1921, a period of three and a half years, admitted 92 cases of rheumatism, carditis, and chorea. Their treatment has been the provision of fresh air, sunlight, warmth, and good food, combined with an amount of rest varying in accordance with the amount of active infection; this entails regular medical supervision and good nursing management to ensure contentment of the children while under considerable restraint. The treatment aims at preventing or arresting the progress of rheumatic infection, especially in the heart. At the end of certain periods, depending at best upon clinical and at worst upon financial considerations, the children are returned home. Subsequently, by means of circulars, the discharged cases are sent for and re-examined in London. In May, 1925, about two-thirds of those circularised arrived for this purpose, and I may here remark that the proportion of patients so responding is bound to fall as time goes on—an illustration of the disadvantages with which one works single-handed, compared with advantages possible under some such system of team-work as I venture to recommend below.

The report falls into two parts: (*a*) The results of observations of the children while in the wards; (*b*) the results of subsequent re-examination of discharged cases.

In estimating results, the subjective sensations of the patients and their parents' opinions are of very slight help, except in severe carditis and in chorea; experience points to the following three criteria as furnishing the most useful indications of progress or the reverse: (1) Quiescence or recrudescence of symptoms; (2) constitutional signs; and (3) cardiac physical signs.

(*A*) *Observations in the Wards.*

(1) *Recrudescence of symptoms* may be summarised as follows:—

(*a*) *Acute Rheumatism.*—There has, in three and a half years, been only one case that has had any severe arthritis with fever, and this was a girl with very severe pancarditis, who died later on. Only one other case complained of occasional pains in the limbs, and this was without fever.

(*b*) *Chorea*, once abolished, has recurred in three cases only—in all of them as a result of a definite emotional upset. In two other cases the movements were never completely got rid of; they appear to be more difficult to check in girls of ample physical proportions.

(*c*) *Tonsillitis* is more common and is troublesome, and the cases are quickly isolated owing to their being very infectious; in the first "epidemic" that occurred the hearts of at least two children seem to have suffered severely.

(*d*) *Simple Pyrexia* occurs occasionally and, as it yields to salicylates in most cases, is probably rheumatic; it has twice been accompanied by fresh carditis.

(*e*) *Scarlet Fever* occurred in one case and was followed by fairly severe scarlatinal rheumatism without further carditis.

(2) *Constitutional signs* are noted as follows:—

(*a*) *Pallor* seldom persists; if it does so it is a bad sign, but "a good colour" is often a sign that flatters.

(*b*) *Weight* goes up in all but rapidly deteriorating cases; only a very rapid putting on of weight can be taken as a really good sign by itself.

(*c*) *Pyrexia.*—The nearer the temperature tracing approaches to a straight line, the better a case appears to be doing.

(*d*) *Heart Failure* occurs only in the severest cases; a heart may be able to respond to a considerable degree of effort while being slowly and progressively infected. Response to effort is therefore no criterion.

(*e*) *Tachycardia.*—The rheumatic poison has an especial effect in producing a rapid and excitable heart-beat, quite apart from gross cardiac lesions; in such cases there is little or no respiratory variation in the pulse-rate. Correct charting of the pulse-rate is of the utmost importance, since the visit of the doctor may cause a temporary tachycardia. There is no effect of treatment so definite as the change, after a longer or shorter period of time, from this rapid excitable pulse-rate, to one of a more deliberate and uneven rhythm, the first sign of improvement being a noticeable slowing of the rate on instructing the patient to expire slowly after taking a deep breath ; as recovery proceeds the sign becomes more and more marked. Digitalis is successful in slowing the rate of these hearts in a certain number of cases, but the effect is usually lost on discontinuing the drug. While it is possible that a slowing of the pulse might also be obtained in children allowed to get up and to go about, I feel that the questions of immunity which determines the progress or arrest of infective carditis are more safely dealt with under the conservative methods of rest in bed.

(3) *Physical Signs in the Heart.*—Dilatation of the heart borders should be regarded, when following an attack of rheumatism, as evidence of an infected myocardium. It is often accompanied by a systolic murmur which sufficient rest in bed abolishes. The mitral diastolic bruits, described by Dr. W. B. Cheadle, are very common and are of the utmost importance in prognosis, especially as regards mitral stenosis and ultimately auricular fibrillation. As in the case of tachycardia, the difficult question of valvular infection seems to me to be more safely dealt with by rest in bed until constant auscultatory signs and a quiet pulse-rate show the endocarditis to have been arrested. Aortic murmurs do not appear to undergo any favourable modification.

The result of the work as organised in the wards is that there is a slow but steady stream of children passing from the rest wards to the convalescent ward. Out of the 92 cases under treatment 73 have been girls ; the average age on admission was 9·3 years, the youngest child having been 4½ years old. The average stay of the patients was six months. Beginning in October education will be given in the wards by a fully certificated mistress.

(*B*) *Examination of Discharged Cases.*

Of 75 cases discharged before the spring of 1925, six had died ; all were cases of severe and advancing cardiac rheumatism and were, practically speaking, sent home to die. Of the remaining 69 cases just two-thirds were re-examined, and of these 46 cases 15 showed, or had shown, subsequent signs of active rheumatism, chorea, or carditis. In eight of these there had been fresh acute rheumatism, shortly after returning home ; in two cases mitral disease had slowly developed along with continual chorea ; in two cases there was progressive evolution towards mitral stenosis in spite of reports of perfect health from the patients and their mothers ; and in three cases there had been chorea off and on for from one to two years without any carditis. The remaining 31 cases had held their own and had had no relapse.

While some of these cases appear to have justified the results of the treatment they have had, one is bound to admit that other cases, who, after a short period of treatment, were withdrawn against advice, had done equally well ; on the other hand, certain cases, thought to have done well at Broadstairs, were disappointments. There are, I think, so many variations in the conditions to which these cases are exposed, that in order to investigate fairly the results of any type of treatment for rheumatism in childhood, it would be desirable to select a series of cases as uniform as possible.

Some of these variable factors may here be reviewed.

(1) Number of attacks of rheumatism before beginning treatment.
(2) Presence or absence and severity of carditis.
(3) Mode of onset of disease—acute, insidious, or choreic.
(4) Home conditions of the patient, especially after returning from treatment. One of my most disappointing cases said that the damp stood upon the walls of her home.
(5) Length of time under treatment.
(6) Performance or otherwise of tonsillectomy as part of the treatment.

Doubtless many of the variations in the onset and virulence of rheumatic infection are bound up with questions of individual and tissue immunity, to which at present we have no answer. Nevertheless, it should be possible by careful selection from a large number of cases to form groups for observation in which all the above variable factors should be as uniform and as favourable as possible. For such a purpose the following organisation would seem to be required :—

(1) A *central building* in London (or other city), by means of which : (*a*) Accurate histories could be obtained from patients' relations. (*b*) Cases could be taken, if desired, by reference from the general hospitals. (*c*) Visitors could report on home conditions and endeavour to get house repairs effected in special cases. (*d*) Physicians could select and group fresh cases, probably giving preference to early cases, as in tuberculosis. They would also be able to re-examine cases returned from rest homes. (*e*) Records could be kept.
(2) *Rest homes* for carrying out treatment.

From re-examination of these discharge cases one cannot fail to learn that the most accurate prognostic signs are to be found in repeated examinations of the heart ; quiescence of symptoms is deceptive, and in America they have learned that even three years must elapse before it can be assumed that a favourable case is likely to be free from recrudescence. Similarly, constitutional signs are unreliable. I saw a boy in May, 1925, who had a really healthy colour, and had recently been running about ; he has had about two attacks of rheumatism yearly since 1921, the heart is greatly enlarged, and shows mitral systolic and diastolic bruits, and an aortic diastolic murmur ; his last attack had been in February, 1925. If, however, by any management, such unfavourably developing physical signs can be arrested, then, as the period of life approaches at which the heart is less susceptible to infection, the chances of an active and useful life are increased.

Clinical and Laboratory Notes.

TWO CASES OF LATERAL SINUS THROMBOSIS.

By DOROTHY J. COLLIER, M.B., B.CH. OXF.,
ASSISTANT, EAR, NOSE, AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL ; REGISTRAR, CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.

THE following cases of lateral sinus thrombosis may be considered worthy of record, as in each instance I performed a radical mastoid operation and ablated the infected lateral sinus without tying the internal jugular vein, with successful results.

CASE 1.—B. E., a girl aged 14, was admitted to hospital with a history of discharge from the left ear for four years. She complained of pain over the left side of the head and in the left ear, and gave a history of attacks of shivering and vomiting. On admission the patient was very ill, with a temperature of 97° F., pulse-rate 120, and she had tenderness over the left mastoid process. A mastoid operation was performed and a large extradural abscess evacuated. There was thrombosis of the lateral sinus down to the jugular bulb ; the sinus was opened and a septic clot evacuated. The jugular vein was not tied. On the following day the patient's condition was still bad, but there had been no rigors ; on lumbar puncture the cerebro-spinal fluid was found to be normal. Two days later the temperature rose to 104° F. and the pulse-rate to 140. She vomited several times during the night. There were no rigors. The wound was reopened and more septic clot was turned out of the lateral sinus. From this date the patient made an uninterrupted recovery.

CASE 2.—I. A., a woman aged 21, was admitted to hospital with symptoms of acute mastoiditis on the left side. Her temperature was 103·6° F. and her pulse-rate 136. A mastoid operation was performed ; the bone was very sclerosed, and a perisinus abscess was present. The lateral sinus was exposed for one inch, and the wall of the sinus was seen to be healthy and felt to pulsate. Her condition improved after the operation for three days, when her temperature rose again. On lumbar puncture the cerebro-spinal fluid was found to be normal ; a blood count gave a leucocytosis of 12,500 per c.mm. Two days later she had two rigors ; the cerebro-spinal fluid was still normal, and the leucocyte blood count was 15,000 per c.mm. The wound was reopened and the lateral sinus was further exposed; the wall was found to be covered with grey granulations. The sinus was opened and a septic clot evacuated; there was free bleeding from both ends of the cut sinus. The internal jugular vein was not tied. Three days later the leucocyte blood count had come down to 6000. She made a slow but uneventful recovery.

Comments.

The tendency of recent writers, particularly in America, in dealing with the surgical treatment of lateral sinus thrombosis, has been to advocate ligation of the internal jugular vein in every case. The two cases here reported show that no hard-and-fast rule should be laid down about the necessity for invariable ligation of this vein. These patients are usually so gravely ill that it is eminently desirable for the surgeon not to undertake measures of greater severity than are absolutely necessary. Mr. Richard Lake has emphasised the importance of speed in carrying out surgical procedures in such cases. Ligation of the internal jugular vein does not necessarily prevent extension of the infection to the systemic circulation because of the establishment of collateral venous circulation. Laurens,[1] moreover, points out that the statistics of ligation and non-ligation show equal percentages of recovery.

I desire to express my thanks to Mr. Lake for the opportunity of operating on these two cases in his wards at the Royal Ear Hospital.

A CASE OF
ATROPHY OF RENAL ORIGIN IN A YOUNG INFANT.

BY CATHERINE CHISHOLM, M.D. MANCH.,
AND
EDITH F. WILLOCK, M.B., B.CH. DUB., F.R.C.S. IREL.

IT seems probable that the following case of renal atrophy in a young infant is worthy of record.

A female infant, aged 5 weeks, was admitted to hospital with a history of dyspepsia and loss of weight. She was an eight-months infant and had been almost entirely breast-fed. On admission she weighed only 4 lb., and showed signs of recent wasting; no cardiac, respiratory, or other abnormalities were detected; the urine was not examined as maintenance of warmth and careful handling were essential in her existing condition.

The patient was given breast milk feeds but failed to make much progress, though dyspepsia was not evident, and after a month she was placed for three weeks in an oxygen cot, in which she breathed air with 40 per cent. oxygen and the accumulation of her own expired carbon dioxide for some eight hours out of each 24.[1] With this treatment satisfactory progress and gain in weight commenced and continued for six weeks after removal from the cot, although during this period the breast milk was discontinued.

Improvement was so satisfactory that the infant was vaccinated, and lactified milk feeds were being changed to simple milk and water preparatory to discharge, when an attack of dyspepsia supervened. The attack was not severe but it apparently sufficed to upset the balance, and for the ensuing eight weeks the infant remained obstinately stationary in weight, and the clinical picture was definitely one of atrophy.

There were occasional manifestations of mild dyspepsia, the appetite was poor, and the skin developed a curiously yellow tinge, though no bile was present in the urine. At this time a blood count showed 3,530,000 red cells and 20,000 white cells, with hæmoglobin 45 per cent. A second period of treatment in the oxygen cot was then given for a month during which some general improvement and gain in weight occurred. Some diarrhœa was present at times. Improvement continued for a short period after removal from the cot, but a relapse then took place, with anorexia, dyspepsia, and general deterioration. Dietetic treatment had no effect, and finally pulmonary complications developed and death ensued (aged 7 months).

The blood count a few days before death showed 5,500,000 red cells, 22,900 white cells, with 55 per cent. hæmoglobin. Von Pirquet reactions were negative, and X rays, at the age of 5 months, showed no bony changes.

Post-mortem examination revealed some pulmonary consolidation, a dilated stomach, enlarged mesenteric glands, and exceptionally small, finely granular kidneys with adherent capsules. Microscopically both kidneys showed well-marked fibrosis and atrophy, due to long-standing chronic nephritis, probably fœtal in origin.

Similar Cases on Record.

Barber[2] discusses ten cases of renal dwarfism and refers to others recorded by Paterson, Fletcher, and others. Greene[3] has reviewed the literature on chronic nephritis in children, and has collected 27 cases. Thursfield[4] has reported a case of chronic interstitial nephritis (? congenital) and renal dwarfism in a girl aged 12½. Barber's cases ranged between 11 and 20 years of age, and three were still alive at the time of writing. In Greene's series the eldest was 10 years old and only three were in the first year of life. In all cases the children were very small and undersized from birth; Barber states that as a rule the lack of development becomes more striking after the sixth or seventh year.

Albuminuria was present in all of these cases in which the urine was examined (26), except one, and in this case the urine was only examined by a nurse; in one of Barber's cases no albumin was present at the age of 3½ years, but appeared later. Bony deformities, mainly genu valgum, were present in eight out of Barber's ten cases; these usually developed later than those of ordinary rickets, but radiologically resembled them. Osseous changes were also present in Thursfield's case, and in those of Greene in which radiographs were taken. Post mortem the kidneys examined were all very small and granular and showed marked chronic interstitial nephritis, probably of long standing.

Commentary.

The case recorded in this note undoubtedly belongs to the class of renal atrophies; clinically, the infant was definitely atrophic, and was, indeed, selected in consequence as a good experimental case in which to observe the effects of oxygen on atrophic infants. It is unfortunate that no record of the presence or absence of albuminuria was made; there was never any œdema or polyuria to call attention to renal disease, and albuminuria may have been absent, as in the case described by Barber referred to above. The absence of osseous changes, as shown by X rays, in the case described may be accounted for by a late development of these changes.

It is extremely uncommon to find any record of this rare condition at such an early age; Greene has collected only three cases under 1 year of age from the literature, and in none of these had any X ray examination been made. Our case suggests that the bony changes arise later, as these have been almost invariably recorded in older children, if examined by X rays.

Manchester.

ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—At a meeting of the governors, presided over by Princess Beatrice, it was decided to reconstruct the old portion of this hospital at Ryde. The scheme, which will cost £15,000, includes the enlargement of the X ray department, which deals with more than 3500 patients annually.

HOSPITAL ACCOMMODATION AT LEEDS.—Dr. J. Johnstone Jervis, medical officer of Leeds, reports that the hospital accommodation of that city is inadequate in the sense that it is badly distributed rather than insufficient. All the voluntary institutions have long waiting-lists, while the Poor-law infirmaries are only partially occupied. "Some of the latter," he says, "are buildings of comparatively modern structure, well situated and well equipped, and would make ideal hospitals for the treatment of the sick of all classes of the community, including those who are able to pay a reasonable fee for their treatment." He therefore suggests that the law should be so altered as to allow of the doors of the Poor-law infirmaries being opened to the whole community.

APPLIED MEDICINE.

Social Aspects of Mental Hygiene. Addresses by FRANKWOOD E. WILLIAMS, C. MACFIE CAMPBELL, ABRAHAM MYERSON, ARNOLD GESELL, WALTER E. FERNALD, JESSIE TAFT. London: Humphrey Milford; Oxford University Press. New Haven: Yale University Press. 1925. Pp. 150. 7*s.* 6*d.*

An Approach to Social Medicine. By FRANCIS LEE DUNHAM, M.A., M.D., Lecturer on Social Medicine, Johns Hopkins University. Baltimore: The Williams and Wilkins Co. 1925. Pp. 242. $4.00.

THE psychiatric social worker is a species peculiar to the North American continent where, however, it flourishes abundantly. In the *Mental Hygiene Bulletin* for June, 1925, there were described courses of instruction in no less than 11 schools, colleges, and universities which are organising summer teaching in psychiatry and mental hygiene for lay women. The students at these courses will for the most part have been college graduates. By this time they have been taught about complexes and fixations, about adenoids and tuberculosis, and some of them have even had some superficial experience of the use of a stethoscope. Thus equipped, they have no difficulty in finding professional employment; courts, prisons, hospitals, asylums, industrial corporations, and innumerable voluntary health agencies demand their services. The average doctor they feel, and perhaps reasonably, is rather less well equipped than themselves to deal with behaviour problems, though he may be consulted when it is desired to rule out adenoids. For the most part they will treat the psychiatrists with respect, for thence comes their learning—but they are a profession sui generis and responsible not to the medical profession, nor to any ministry of health, but only to the lay organisation which happens to employ them. The lectures collected under the title Social Aspects of Mental Hygiene are examples of the tuition which the psychiatric social worker is getting; selected examples it must be admitted, for the writers are among the best known and rightly respected of American mental hygienists. It is as such that English doctors should read them, not expecting to learn anything about the origins of behaviour that they had not heard of before.

Dr. Dunham's book goes much deeper. A practising psychiatrist, living, one imagines, in an atmosphere of philosophy and sociology, he has been brought to examine very fundamentally the tendencies both of social service and of psychiatry. "The aim of preventive science, applied to welfare," he finds, "embodies a synthetic reconstruction of the existing situation, in the accomplishment of which an analysis of the various social fields is fundamental." Society is a laboratory wherein, if we would learn, the experimental method must be rigidly applied and the resulting knowledge reduced as far as may be to comparable, measurable, data. Among the basic factors of social life which we must learn increasingly how to estimate—and estimate quantitatively—are health, intelligence, and character. The greatest of these and the hardest to assess is character. But the analytical method, derived from much experience and insight, which Dr. Dunham describes, does indeed constitute an approach. In spite of an unfortunate addiction to four-syllable words, Dr. Dunham's book is easily read and full of stimulating and well-organised ideas.

Personal and Community Health. By CLAIR ELSMERE TURNER, Associate Professor of Biology and Public Health in the Massachusetts Institute of Technology. St. Louis: C. V. Mosby Co. 1925. Pp. 426. $2.50.

THIS book differs from the numerous other college text-books of hygiene at present rife in America, in that it combines public with personal health. In this respect it registers an advance. The layman is likely to get a more wholesome as well as a more useful knowledge of hygiene when he considers the subject as a social reformer rather than as a valetudinarian. Moreover, as this text-book shows, it is possible to write more convincingly about the principles of preventive medicine than about the rules of private well-being. The latter are so numerous, so varied, many of them so ill-founded, that any writer must be constantly on his guard lest he preach to the less critical college student doctrines that he knows would be challenged in a society of physiologists. Such a doctrine is the rule that we should drink six glasses of water a day, and it is here presented (p. 33) without regard to the heat of the day or the activity of the drinker.

Three-quarters of the book is occupied with the teaching of preventive medicine. The outline followed is as orthodox as the teaching. There is a short history of preventive medicine in which the origins of epidemiology are curiously introduced after the work of Pasteur. There is very properly a chapter on immunity which contains some ingenious guesses, as, for example, that anaphylaxis explains a possible inherited susceptibility to tuberculosis; chapters on water-supply and waste disposal, which are the best in the book, and as an appendix the 1916 report of the Committee on Standard Regulations of the American Public Health Association, which describes briefly the commoner communicable diseases and the methods of control then available.

The book contains few errors for a first edition, is well printed and bound, and as readable as college text-books are wont to be.

SURGERY.

A Synopsis of Surgery. Seventh edition. By E. W. HEY GROVES, M.S., M.D., F.R.C.S., Surgeon to the Bristol General Hospital, and Professor of Surgery, Bristol University. Bristol: John Wright and Sons, Ltd. 1925. Pp. 671. 17*s.* 6*d.*

THREE years have elapsed since the sixth issue of this useful synopsis, and throughout the book there is frequent evidence of careful revision, the subject-matter as presented being absolutely abreast of modern surgical advances. The section on abdominal disease, by Mr. D. G. Tasker, is a good example of the general standard of excellence. It is pleasant, for example, to find Barnard's classification of subphrenic abscess clearly given, and a compendious account of diverticulitis of the colon. A number of new line drawings are designed to elaborate the necessarily short description of certain subjects. It is really extraordinary what an amount of up-to-date surgical knowledge Prof. Hey Groves has compressed into so small a volume.

Infections of the Hand. Fifth edition. By ALLEN B. KANAVEL, M.D., Professor of Surgery, Northwestern University Medical School; Attending Surgeon, Wesley Medical Hospital, Chicago. Philadelphia and New York: Lea and Febiger. 1925. Pp. 449. $5.50.

IT was largely owing to the work of Kanavel in Chicago that this subject began to attract more widespread attention in this country, and his monograph is now well known. The book is happy alike in the practical research upon which the clinical work is founded and in the presentation of the diagnosis and treatment of these grave infections. The present edition has been improved in one very important respect. In previous editions, though the more serious disasters following inefficient treatment were described, their treatment (apart from prophylaxis) was not made very clear. A new section has now been introduced, dealing exhaustively with the treatment of stiff fingers, large scars with contractures, and so on. Continuous elastic traction on fingers fixed either in flexion or extension is excellently illustrated. How to make good skin defects from the abdominal wall is also given in greater detail. The book should certainly form part of the student's and practitioner's armamentarium.

Diseases of the Rectum and Pelvic Colon. Second edition. By MARTIN L. BODKIN, M.D., F.A.C.S., Rectal Surgeon, St. Catherine's Hospital, Associated Surgeon, Broad Street Hospital, and late Rectal Surgeon of the Bushwick, Williamsburg, and St. Mary's Hospitals, New York. New York: E. B. Treat and Co. 1925. Pp. 487. $6.

THIS edition is improved by the addition of three chapters and by general revision. There is a new chapter on the relation of the intestinal flora to the simple catarrhal diseases of the colon and one on the irrigation of the colon, which emphasises the principles of a treatment which has been much abused. The author recalls the original and correct technique and rationale. There are admirable introductory chapters on general examination of the patient which will teach the student how to approach a case of rectal disease, and no reader can forget the value of digital examination. The stress rightly laid on this recalls the teacher who, for the sake of his students, has a finger-stall hanging at every bedside. The work of English surgeons, it is pleasant to find, has not only been noticed in America, but is evidently thought worth mention in a text-book. Both students and practitioners will find this well-printed and illustrated book useful.

Minor Surgery. By L. R. FIFIELD, F.R.C.S. Eng., Surgical First Assistant and Registrar; Demonstrator of Minor Surgery, London Hospital. London: H K. Lewis and Co., Ltd. 1925. Pp. 431. 12*s.* 6*d.*

THE author has yielded to the importunities of his friends in writing a book on minor surgery as it is taught at the London Hospital and the interest centres largely in the local colour of the teaching. He closely follows Kanavel in treating infections of the fingers, and this section might with advantage have been given in even greater detail. There are numerous illustrations and the line-drawings are not uniformly good. The book will have to compete with a considerable number of other handbooks on minor surgery already on the market.

MALIGNANT DISEASE OF THE TESTICLE.

By HAROLD R. DEW, F.R.C.S. London: H. K. Lewis and Co., Ltd. 1925. Pp. 168. 21*s.*

THIS book is the author's Jacksonian essay on the pathology, diagnosis, and treatment of testicular new growths. After dealing with the anatomy and development of the testicle he discusses, what has long interested and at the same time puzzled pathologists, the morbid anatomy and histology of new growths of the testicle. The multiplicity of references given in this chapter is alone sufficient to show the industry with which the author has foraged amongst works bearing on this subject, and taking into consideration the confusion that still exists, his method of classification and description is remarkably clear. In the final chapters dealing with prognosis and treatment he puts in a strong plea for the radical operation. In his opinion the results of simple orchidectomy have long been a reproach to surgery, and in all cases, except those in which a palpable mass can be felt, an effort should be made to remove the lumbar glands as well as the diseased testicle. Although far removed from the testicle the glands are readily accessible, and in about 60 per cent. of cases admit of removal. The work contains many excellent illustrations and five coloured plates, and is certainly the best monograph on this subject that we have come across in the English language.

EMPLOYMENT AND WELFARE OF JUVENILES.

A Handbook for those Interested in Choice of Employment and After-care. By O. BOLTON KING. London: John Murray. 1925. Pp. 244. 6*s.*

THE theme of this book is the after-care of children who have passed the school age, and probably most readers will be surprised at the very wide net spread by after-care agencies, whether official, through State or local municipal provision, or through more or less private non-official societies. In the author's own words, "After-care takes the whole of the youth's life within its province, looks after his education, his amusements, his moral health—aims at making the man and the citizen." And besides this general welfare movement, there are the numerous "choice of employment" schemes, which are aimed at fitting square pegs into square holes. In respect to these Britain lags behind Germany, Belgium, and the United States, but in matters of general social welfare Britain may fairly claim to lead. The author deals with the subject in a very comprehensive way; few agencies can have escaped his notice. On this account the book is invaluable to all social workers. Its chief scientific interest is in dealing with vocational selection by means of tests. It is already clear that general intelligence tests alone are of little value, that tests of specific capacities are essential, and, in addition, that temperamental qualities require study. Having decided what specific capacities are required in any particular branch of trade, and having devised certain tests for these qualities, there still remains to discover how far the results obtained correlate with the actual working capacities of the workers. Much experimental work, therefore, is still necessary, and, as Mr. King points out, even with a perfect system of tests it not infrequently happens that the work for which a man has great aptitude is not congenial to him. Mechanical efficiency must be supplemented by contentment. An appendix gives valuable information regarding a large number of common trades.

The practitioner called upon to express opinions on the physical fitness of youths for certain trades will find here a basis for a much wider view than the purely medical.

NURSING.

Handbook for Queen's Nurses. First edition. By "Some Queen's Superintendents." London: The Scientific Press, Ltd. Pp. 76. 1*s.* 6*d.*

A HANDBOOK of district nursing has long been a desideratum, and this one, written by "Some Queen's Superintendents," although a modest volume, should help trained nurses who are beginning work on the district. So interesting is the reference to the history of district nursing that one regrets its brevity. The chapter on the duties of the district nurse reveals at once the enormous opportunities presented to those who undertake the nursing of the sick in their homes. "Her task is not only the treatment of disease but the education of her patient and his friends in the essentials of hygiene, so as not only to prevent all avoidable infection, but to raise the standard of health in each household she visits." It is this aspect of district nursing that makes it attractive to nurses whose gifts in these directions fit them for posts of responsibility.

A Reference Handbook for Nurses. Fifth edition. By AMANDA K. BECK, R.N. London and Philadelphia: W. B. Saunders Company, Ltd. Pp. 288. 7*s.* 6*d.*

THIS handbook of convenient size for quick reference should achieve the end for which it was designed, being well produced and containing well-selected information invaluable both to student nurses and to private nurses called upon to meet emergencies. The subject-matter is based upon a collection of notes made by the author throughout her training and nursing experience, and is obviously the result of intelligent observation and the careful record of facts. In addition to the notes collected are several articles by eminent physicians and superintending nurses, and the whole comprises a book eminently suitable to the needs of a nurse, and one which in time would come to be regarded as a friend and support. The chapters on the Preparation of Foods and Food Constituents are noticeably good, and there are a few clear illustrations.

Medikamentenlehre für Krankenpfleger und Krankenschwestern. Fifth edition. By Dr. PAUL FLEISSIG, Apothecary to the Hospital and Lecturer in Practical Pharmacy in the University, Basle. Berlin and Vienna: Urban and Schwarzenberg. Pp. 197.

THIS book should form a useful addition to a nurse's library. It is concerned with the drugs and apparatus connected with drugs used in hospital and in practice, and gives a simple account of their origin and use which will make the work of the nurse more interesting. It is by no means a book to be learnt off by heart, but is full of useful facts and hints, given by one who likes to have things done properly and who has at his command a large number of contrivances to meet contingencies arising in the wards. The chapter on Winke, the expressive German word for "tips," has evidently been congenial work to the author. We are not astonished to note that the work has reached a fifth edition.

THE LIVING EYE.

Microscopie de l'Œil Vivant. Diagnostic Précoce et Sémiologie des Affections du Segment Antérieure de l'Œil. Par F. ED. KOBY, Bâle. Paris: Masson et Cie. 1924. Pp. 240. Fr.25.

Slitlamp Microscopy of the Living Eye. Early Diagnosis and Symptomatology of Affections of the Anterior Segment of the Eye. By Dr. F. ED. KOBY. Translated by CHARLES GOULDEN, O.B.E., F.R.C.S., and CLARA LOMAS HARRIS, M.B. London: J. and A. Churchill. 1925. Pp. 221. 10*s*. 6*d*.

Dr. Koby's treatise on the use of the slitlamp, especially as it is now available in English, should prove of great value to ophthalmologists interested in what is a most promising innovation in methods of examination of the eye. The slitlamp is rather more of a novelty in this country than it is abroad, and until lately all the apposite literature has been in German. It was avowedly in view of this that Dr. Koby wrote his book for the French ophthalmologist. He has produced a clearly written work in a language inherently suited to the expression of scientific thought, a book which no one interested in the microscopy of the living eye can afford to miss. Precise details of apparatus and technique are given with explanations of the optical conditions present. Certain points, such as the thermal currents in the anterior chamber, the structure of the lens, and the changes in pigmentation of the cornea, are dealt with more fully than in any other book on the subject. The illustrations are good, but lose something in the French edition by the type of paper on which they are printed. In the English edition this fault disappears.

The translators have had a difficult task in dealing with terms of which the English equivalents were often doubtful, but there are a few avoidable errors. On p. 142, the sentence beginning, "In this case the design of the sutures . . . ," conveys a meaning the opposite of the French, and three pages later, dealing with the lens shagreen, the translators use "spherules" for "éléments," thereby losing the nuance of vagueness which is desirable, since these objects are really only appearances. "Markings" would perhaps convey the author's meaning better. These little defects scarcely detract from the usefulness of the English edition, which is on the whole a faithful rendering, and has in one or two particulars improved on the original. The points of the lamp on p. 16, for instance, are brought out much more clearly than in the figure on p. 24 of the French edition, which it replaces. The description of Fincham's apparatus brings the first chapter of the English edition fully up to date.

MORE THINGS THAT MATTER.

By Lord RIDDELL. London: Hodder and Stoughton, Ltd. 1925. Pp. 318. 7*s*. 6*d*.

THIS volume is made up of articles which appeared originally during 1922–24 in *John O'London's Weekly*, and which are now republished in response to requests from readers who have desired their issue in more permanent form. The book is uniform with a previous volume, "Some Things that Matter," whose witty common sense over a wide range of subjects was pointed out in our columns upon its appearance.

None of the chapters in the new volume has any strictly medical bearing, save perhaps two which make up a tolerant discussion of that controversial subject, alcohol. Considering it now as a poison and now as the reverse, Lord Riddell's attitude is almost startlingly fair. He writes as one whom teetotalism suits, "having been accustomed to it all my life," but, though fully aware of the evils and dangers that follow abuse, or even use by the suggestible subject, he is so unbiased as to ask at the conclusion of the first of these chapters the following question: "One thing is certain; a teetotal world would be a very critical one. Would this make for increased happiness? I wonder!" The second of the chapters notes that the temperance movement in this country, as in the United States, has been a necessity arising out of social exigencies created some hundred years ago, when to abstain from intoxicants was almost a social slur. In this little discourse misconceptions regarding prohibition in America are set right, particularly the notion that the legislation was hasty or panicky; while it is still on trial the author, like a sound lawyer, comes to no decision on insufficient evidence as to whether its great object—namely, the increased efficiency of workmen—has been obtained. But he brings to notice the fact which too often escapes attention, that we in this country have for some years been engaged in considerable experiments towards, at any rate, the profound moderation of alcoholic habits. The figures that he quotes are, in his own words, imposing and gratifying:—"the production of beer and spirits has fallen nearly 50 per cent. in ten years, and the proceeds of taxation have risen from £33,000,000 in 1910 to £155,000,000 in 1923. Delirium tremens has practically disappeared, and the death-rate from alcoholism has been largely reduced."

A similar knowledge of detail and fairness of judgment is exhibited by the author through some 40 small chapters, all illustrating pregnant questions and supplying clear-cut and pithy reflections in answer.

JOURNALS.

THE JOURNAL OF PHYSIOLOGY. Vol. LX., Nos. 1 and 2. 1925.—The Influence of O_2-tension in the Inspired Air upon the O_2-tension in the Tissues, by J. Argyll Campbell. It is still generally believed that the O_2-tension in the tissues is nil. The previous researches of the author on the injection of gas under the skin and into the abdominal cavity of rabbits and cats showed that the normal O_2-tension under the skin is about 20–30 mm. Hg, and in the abdominal cavity about 30–40 mm. Hg. These tensions may be regarded as the tensions present in the fluids which exist immediately outside, and bathe the cells of the subcutaneous tissue and the cells of the peritoneum of the abdominal cavity Decrease of O_2-tension in the air breathed markedly decreases the O_2-tension in the tissues. Increase of O_2-tension in the air breathed markedly increases the CO_2-tension in the tissues, probably because the increase of O_2-tension in the blood decreases the rate at which

CO_2 is removed from the tissues; perhaps the respiratory centre is also concerned.—The Direct Action of Insulin on Fat Metabolism, by H. S. Raper and E. C. Smith. The possibility that insulin might, in addition to its influence on carbohydrate metabolism, exert a direct action on fat metabolism is suggested by the fact of the immediate reduction of lipæmia and acetonuria in the diabetic on administration of insulin. Direct evidence of the actual synthesis of fat under the action of insulin has never been obtained. The views on the subject are conflicting. The authors used mice, as their small size permits of an estimation of the total fat in the body, and they found that in decapitate eviscerate animals, with constant infusion of glucose, no change in the fat-content of muscle occurred under the action of insulin. The evidence obtained does not support the view that fat synthesis in the liver is associated with insulin hypoglycæmia.—The Effect of Pituitrin on the Fatty Acid of the Liver, by R. Coope and E. N. Chamberlain. It was found that injection of extract of posterior lobe of the pituitary body in rabbits and rats is followed by a well-marked increase in the amount of fatty acid in the liver.—Insulin and the Pituitrin "Fat Liver," by R. Coope. The pituitrin effect described in the previous paper—fatty infiltration of the liver—is not accompanied by damage to the liver cell, nor do the injections cause hyperglycæmia or glycosuria. A single dose of insulin given simultaneously with pituitrin profoundly modifies, and, in many cases, completely prevents the pituitrin effect on the liver-fat—evidence of an antagonism, probably of significance in the normal animal.—The Mechanism of Pancreatic Digestion—the Function of Secretin, by J. Mellanby. A secretion of pancreatic juice may be evoked by appropriate stimulation of the vagus only. Vagal juice is generally scanty in quantity, but rich in proteins and enzymes; secretin juice is copious in quantity, but relatively poor in protein and enzymes. The author determined the quantitative composition of this juice under a variety of conditions. The hypothesis is put forward that the enzyme content of pancreatic juice is determined by the vagus nerves, whereas the quantity of bicarbonate solution in which these enzymes are contained is determined by secretin. On this hypothesis secretin may play a subsidiary part in pancreatic digestion, since it only ensures the presence in the intestine of an optimal reaction for the activity of the pancreatic enzymes.—The Influence of the Spleen in Carbon Monoxide Poisoning, by J. Barcroft, C. D. Murray, D. Orahovats, J. Sands, and R. Weiss. In an atmosphere which receives a continuous accession of coal-gas it was found that guinea-pigs from which the spleens have been removed die sooner than either normal guinea-pigs, those from which omentum has been removed, or those from which one horn of the uterus has been excised. Having regard to the fact that in fatal pressure of carbon monoxide the spleen contracts, expelling its contents into the blood, it is suggested that the longer life of the normal animals is due to this accession of hæmoglobin into the blood. The percentage saturation of the blood with CO is almost the same in all the categories of animals.—The Relation in Diuresis between Volume of Urine and Concentration of a Diuretic with the Influence of Temperature upon It, by E. J. Conway. The experiments were made on rabbits under urethane narcosis; the urine was collected from a bladder cannula, and the necessary injections given through the jugular vein. In an animal which has received a large injection of glucose it was found that the rate of flow of urine and the concentration of glucose are related to one another by a formula which is given by the author. A similar formula is found to apply to the concentration of chloride and the rate of flow in saline diuresis. The effect of body temperature on the constants in these formulæ is to cause an increase of 10 per cent. per degree. A similar increase is found with urea.—The other papers are: On the Effects of Different Salts on the Heat-production in Muscle, by E. Sereni. Hæmochromogen and the Relation of Protein to the Properties of the Hæmoglobin Molecule, by M. L. Anson and A. E. Mirsky. The Maximum Work of the Several Muscles of the Forearm, by J. H. O. Reijs, and a Closed Circuit Heart Lung Preparation, by I. de Burgh Daly, to show the effects of alterations in blood volume. An increase in the volume of circulating blood produces, with the exception of minor differences, the same effect as an increase of venous inflow in the open circuit heart lung preparation.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XXII. July–September.—In his paper on Scarlet Fever, with Special Reference to Susceptibility as Determined by the Dick Intracutaneous Test, which forms his M.D. thesis for the Queen's University, Belfast, Dr. W. A. Brown records his observations on 487 cases of the common infectious diseases—namely, scarlet fever, diphtheria, whooping-cough, measles, rubella, and varicella, on which he performed the Dick test. His principal conclusions are as follows: (1) The Dick test is an index of susceptibility and immunity to scarlet fever. (2) It is a valuable aid to diagnosis. A *strongly* positive reaction in the first 48 hours of a scarlatiniform eruption should make one hesitate before forming a diagnosis of scarlet fever. (3) When a patient who has recently shown a positive Dick reaction develops a scarlatiniform attack the reappearance of the red area at the site of the original inoculation confirms the diagnosis of scarlet fever. (4) Age-susceptibility for scarlet fever is highest at the pre-school age, whereas age-incidence is greatest during the first few years of school life. Immunisation, therefore, if adopted as a prophylactic measure in State medicine, should be carried out in the first few years of life. (5) The Dick test confirms the well-recognised fact that an attack of diphtheria increases the patient's susceptibility to scarlet fever. (6) The use of different dilutions of toxin may show widely divergent results. The use of a 1 in 6000 dilution seems to underestimate the susceptibility, while the use of a 1 in 1000 dilution tends to overstate the incidence.—Dr. Vincent Coates contributes a paper on Lipodystrophia, in which he records two personal cases in boys aged 7½ and 7¾ years, with notes on all the previously reported cases arranged in tabular form. He points out that the cause of this curious condition is entirely obscure. With the exception of a case reported by Napoleon Boston no claim has been made of cure or arrest of lipodystrophia.—Dr. Norah H. Schuster records a case of cerebral degeneration in an infant, in which the symptoms closely resembled those of a case reported by Paterson and Carmichael in 1924, owing to the onset of anorexia, amentia, and muscular weakness at an early age, a rapidly fatal issue and amaurosis. Pathologically the essential lesion was the same in all three cases—namely, a degeneration chiefly localised in the basal ganglia, combined with excessive production of blood-vessels and neuroglia. Wilson's disease could be excluded, as there was no cirrhosis of the liver. Dr. Schuster attributes the condition to a toxæmia of unknown origin, with no evidence of bacterial infection.—Dr. W. M. Feldman reports two cases of Occlusion of Bile-Ducts in Infants, whose ages were 8 weeks and 10 weeks respectively. He maintains that if surgical measures were adopted immediately the jaundice manifests itself they might be successful.—Dr. Angelica Panayotatou, of Alexandria, records a case of Ascaridiasis with Benign Jaundice in a boy of 8 years. The ova of *Ascaris lumbricoides* were found in the stools, and under treatment by santonin and calomel pills, followed by castor oil the next morning ten round worms were passed, and rapid recovery took place. The writer urges that in Eastern countries, especially those in which intestinal parasites are so frequent, the possibility of their presence should be considered in all illnesses of the intestinal canal. — The abstracts from current literature are devoted to ophthalmology.

Reports and Analytical Records.

(1) CHOCOLATE "IODOSTARIN"; (2) ALLONAL.

(Hoffmann-La Roche Chemical Works, Ltd., 7–8, Idol-lane, E.C. 3.)

(1) Chocolate Iodostarin is a preparation for the administration of iodine in the prophylaxis of goitre. The chocolate tablets in which the drug is contained are sold in boxes of 50 which, on experience gained in Switzerland and the United States, appears to be a sufficient quantity for prophylactic employment in the case of a child or young person for a period of six months. Each tablet contains the equivalent of 5 mg. of iodine, and it is necessary to note the distinction between this preparation and ordinary iodine tablets which are employed in syphilitic affections.

(2) Allonal was reported upon in The Lancet early last year. The full name of this preparation showing its composition is allyl-isopropyl-barbituric acid with phenyl-dimethyl-amino-pyrazolon. It is an hypnotic and analgesic which can be employed in substitution for morphine as it seems to have no habit-forming propensities. Numerous clinical reports have been published in the American medical press but the drug is still new to the English market, for which reason it may be serviceable to recall its characteristics. American experience goes to support the claims of the manufacturers that it is a remedy of real value for controlling insomnia and pain. As the preparation contains a derivative of barbituric acid it comes within the scope of the Poisons Schedule and is only supplied to registered practitioners and pharmacists. Recent evidence has been sent to us of the particular value of Allonal in certain cases as an hypnotic, for American physicians have put it to practical use in the breaking of drug addictions such as morphinism and alcoholism, although they allow that it is too early to speak dogmatically. Certainly further experience here would be worth recording, and there seems to be an opening for some extended inquiry under controlled circumstances.

(1) DIBROMIN; (2) SILVER NITRATE SOLUTION CAPSULES; (3) STORAXOL; (4) OLGAR.

(Parke, Davis and Co., Beak-street, London, W. 1, and Detroit, Michigan, U.S.A.)

(1) Dibromin is a crystalline synthetic compound containing approximately 56 per cent. of bromine in loose combination. When its solutions are brought into contact with infected tissues the bromine is slowly liberated and exerts a powerful germicidal action. It is stable in the dry state and solutions are easily made of definite strength; these do not stain or irritate and are practically non-toxic. Dilute aqueous solutions, ranging in strength from 1 in 10,000 to 1 in 2500, may be applied by continuous irrigation in the treatment of extensive wounds or ulcerations, and for infections of the urethra, bladder, or uterus. Weak solutions are suitable for use as mouth washes and as collyria in eye infections. The preparation is supplied in 6 gr. capsules (in bottles of 10 or 50 capsules) for convenience in making solutions without weighing—the contents of one capsule added to 7 pints of water forms a 1 in 10,000 solution.

(2) Silver nitrate solution capsules provide in aseptic condition the 1 per cent. solution of nitrate of silver for application to the eyes of infants at birth. They are formed of a special wax, and each contains about 5 ♏ of the solution, which is easily expelled by pressing the capsule between thumb and finger after an aperture has been made with a sterile needle. Two of these capsules are supplied in a tin together with a puncturing needle and directions for use.

(3) Storaxol is a combination of storax, resorcin, menthol, camphor, carbolic acid (5 per cent.), and precipitated sulphur in an emollient base. As the ointment is penetrative it forms a good parasiticide. Its antipruritic, antiseptic, and analgesic properties indicate its use in chronic eczema, ringworm, pruritus, urticaria, impetigo, psoriasis, scabies, and parasitic affections of the scalp. It can be employed as a serviceable dressing for foul ulcers and in the itching of piles. It is supplied in convenient collapsible tubes, also in jars containing 1, 5, or 10 pounds.

(4) Olgar consists of highly purified liquid paraffin emulsified with agar. It has the appearance and consistence of thick cream and is agreeably flavoured. The paraffin is rigorously tested to ensure freedom from injurious by-products. The administration of Olgar is indicated in cases of chronic fæcal stasis and the various forms of auto-toxæmia resulting therefrom; in catarrhal conditions of the intestine and hæmorrhoids. Its lubricating and therefore soothing action is purely mechanical; it softens the intestinal contents and facilitates peristalsis. The dose for an adult is one tablespoonful night and morning. It is supplied in 16-ounce bottles.

LACTOBYL.

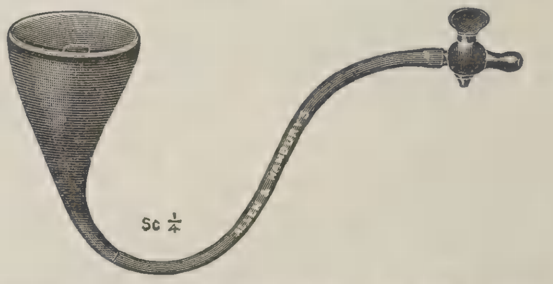
(J. Legrand, 21, Rue Theodore-de-Banville, Paris, 17e; and The Continental Laboratories, Ltd., 22d, Ebury-street, S.W. 1.)

This preparation is a combination of agar, biliary extract, extract of the intestinal glands, and lactic ferments, and is designed to regulate the biliary and intestinal secretions, replacing the habitual use of purgatives. A physiological theory, set out by the literature, which meets the ætiology of every case of chronic constipation, would have some difficulty of establishment, but the value of agar on intestinal residues is well known, while promotion of a flow of bile is the object of all preparations similar to lactobyl, and there is evidence that that object is achieved. It is supplied in tablets in which the dosage is calculated so that one to six tablets can be taken without causing any colic. The treatment should be commenced with one or two tablets, the dose being increased or diminished according to the results.

New Inventions.

MODIFICATION OF DE RIBES'S BAG.

The illustration shows a modification of De Ribes's bag which I have suggested. By a special device the broad end of the bag, when filled, is concave, so that it does not displace the fœtal head. The pressure also is evenly distributed outwards against the inner side of the cervix, thus producing more speedy dilatation. The object of this, like any other form of De Ribes's bag, is to play the part of the membranes in those cases where the membranes rupture early in labour. The bag, when folded, can be introduced into the uterus when the cervix is the size of a shilling by means of long ovum forceps. It is pear-shaped, $2\frac{1}{4}$ in. in diameter at the broad end, and 4 in. long, and it is made of rubber of medium thickness. When the bag has been introduced a Higginson's syringe is fitted to the tap and the bag partially filled with water. The bag remains in position until the cervix is fully dilated.



The bag can be obtained from Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, W.

THE LANCET.

LONDON: SATURDAY, OCTOBER 3, 1925.

YESTERDAY, TO-DAY, AND TO-MORROW.

We publish to-day three of the introductory addresses delivered this week at the opening of the winter session of the Metropolitan medical schools, when Prof. E. A. Gardner introduced his audience at Westminster Hospital to the very beginnings of medical art in ancient Greece, while Major J. H. Beith spoke to the students at Guy's Hospital on the necessity of cultivating in professional life sympathy with the personal attributes of the sick subject. Major Beith, it will be seen, draws his humorous and pointed illustrations from the working of a Rolls-Royce car, while Prof. Gardner lays stress on the influence of the mind over the body as evidenced in the days when not to believe in magical manifestations would have been a confession of ignorance, and the two addresses between them illustrate the practice of medicine as carried on in conformity with accepted knowledge throughout a period of over 2000 years, during which time we cannot fail to see that human nature has remained much the same thing, and that the part played by medicine has shown a similar applicability to circumstances. The more intimate that the doctor's comprehension is of the patient's mental make-up, the more successful will be his choice and application of remedies for his physical ills. So it was in the yesterday of ancient Greece, so it is to-day in our hospital and private practice, and so it will be in any of those great developments of to-morrow, in which the progressive nature of our science and art warrants belief.

Prof. Gardner in his disquisition on the cures of Æsculapius surveys common ground upon which the students of archæology and medicine meet, and it is archæology which has revealed to medicine the sources of the wisdom of Hippocrates, the Father of our calling. The ancient Greek records, notably those at Epidaurus, though compiled apparently at one date, were based upon votive offerings received over a long series of years, and the traditional wisdom thus placed at the disposal of Hippocrates led to the compilation of the first great medical system. In this the practice of medicine was for the first time based upon the principles of inductive philosophy, and while the knowledge of anatomy, of physiology, and, therefore, of pathology was defective, the observations on the natural history of disease were masterly. He was evidently able to sift the wheat from the chaff in the votive offerings, as well as in the many contributions from all sorts of sources, authoritative and other, which must have gone to the compilation of the numerous treatises. The story was carried on, as all know, by the development of medicine in Greece, the rise of the Alexandrian school, and the teachings of Celsus and especially of Galen, and when after the dark ages the classical literature was brought to light, all that stood the proof of clinical trial remained as the structure upon which have been erected the immense developments of the scientific medicine of to-day. Here fundamental discoveries have worked veritable revolutions in conception as in practice, but the mind of man in relation to his body remains substantially unaltered. We are reminded by Prof. Gardner that Sir Clifford Allbutt estimated that in the Æsculapian centres by pomp, splendour, and enchantments the senses of the patients were captured and the springs of nervous energy unsealed. The same thing happens to-day; and while the mass display of the power of suggestion, that can be seen at Lourdes, is in many respects a return to the methods at Epidaurus as described by Prof. Gardner, the need for estimating the relations between the physical and mental qualities of the patient is to-day recognised by every medical practitioner as of paramount importance. The eulogy of Sir Clifford Allbutt which Sir Arthur Keith gives in the third address which we publish suggests the ideal fusion of the man and the student which makes the physician. His plea for disciplined minds is appropriate, and a sense of proportion is stimulated by his statement that 20,000 years ago European man was as well equipped in size and form of brain as he is to-day.

Major Beith's address, though deliberately cast in a light and humorous mould, conveys a similar serious message—a message foreshadowed in its title, for his thesis is that, while no force or attractiveness of personality can compensate the doctor for ignorance, yet, unless the doctor's personality be sympathetic he will be deprived of an invaluable adjuvant to his labours. Major Beith's counsel to medical students that, if they want to get on in the world quickly, they must advertise, would have been dangerous in its implications if he had not immediately qualified his words by making hay of the methods employed in the specialised world of advertising, while his comments on the art of handling patients conceal real shrewdness under a humorous cloak. And his closing words, when applied to the responsibilities which lie upon the shoulders of the medical practitioner, will find general endorsement.

EXPERIMENTAL EPIDEMIOLOGY.

In pre-bacteriological days epidemics were things of themselves, with origins, structures, and natural histories characteristic of each variety in the same way that each kind of animal and plant has a specific anatomy and specific habits and relationships to the rest of the world. With the recognition of parasites, epidemics were, as it were, materialised into reactions between the host on the one hand and the bacillus or protozoon on the other; the "cause" of an epidemic of a disease became the parasite which was related to that disease. Writers like Hirsch and Creighton were looked on as curious out-of-date mystics, and Sir William Hamer's gentle raillery failed to convince as many bacteriologists as it should that they had no real explanation of the natural phenomena in their talk of cultures and immunity. Experience has shown, as it has so often done before, that the flood of the new knowledge of parasites did not of itself explain all that its devotees expected and by implication claimed, and as more accurate experience of the facts of epidemics has accumulated it has become clear that the older point of view really needed attention. That the older epidemiology is really discrepant with parasitology is unthinkable if it is assumed that parasites are a necessary factor in the causation of the diseases concerned; it is evident, however, that much more knowledge is required before the two lines of thought and explanation can be brought into harmony. Observation has its limits of usefulness in unravelling such problems; there is, indeed, little hope of success unless the questions can be dissected and simplified by experiment. The recent progress of experimental epidemiology, associated chiefly with the work of Prof. W. W. C. Topley in this country and of Dr. L. T. Webster in America, is, therefore, to be heartily welcomed and their work deserves close study. In the latest instalment[1] of the Manchester work the careful experiments made by Prof. Topley are analysed and discussed by Dr. M. Greenwood as if they were the returns of a medical officer of health, and their joint paper makes an exceptionally readable and interesting document. The particular infection examined is the pasteurellosis of the mouse, and the particular problem here dealt with is the effect of adding normal animals to an infected population. It had previously been shown that if an epidemic is started in a mouse community it spreads through it and then dies away, leaving a certain number of survivors, and that if at this stage a number of normal animals are added to the community the epidemic blazes up again and involves not only the fresh mice but also the survivors of the first outbreak. In the present experiments fresh normal animals were added at various intervals of a few days, and in this way an epidemic was maintained for more than three years. The mortality was not regular but in waves, usually of a length of about three weeks, though sometimes three times as long, and the course of the mortality varied with the number of fresh mice coming into the population and the rate at which they came in. The outstanding fact, as the authors point out, is the encouragement of an epidemic in a community by the immigration of non-infected individuals. It has generally been assumed that the admission of normal animals to an infected herd is not dangerous to that herd (though it is, of course, dangerous to the normals coming in). This is shown to be unsound. The explanation remains to be worked out. At present one can assume only that in the decline of an epidemic some sort of balance is reached between the parasites and the hosts such that the parasites can do no further harm unless they can get into some normal non-immune individuals in whom they can breed up a race which is capable of attacking the resistant residue of the epidemics. These are questions at the very fundamentals of epidemiology, and we may look to the experimental method to help substantially towards their solution. Meanwhile we may reflect on the wisdom of the ancients who knew that the best thing to do with an epidemic was to shut it up and have nothing to do with it. We now know that they were thinking of others as well as of themselves.

SCARLATINAL OTITIS.

Mr. T. B. Layton's report[2] to the Metropolitan Asylums Board on ear disease in scarlet fever is a continuation of that sent in by him in July, 1921, as a result of one year's work, and the present report deals with the 13 months from September, 1923, to September, 1924, inclusive. In that period 290 scarlet fever patients suffered from suppurative disease of the middle ear, a percentage of 8·61; the incidence in scarlet fever of simple type was 7·13, and in septic scarlet fever 24 per cent.; the statistical tables also show that otitis is more frequent, and recovers less rapidly, in the first quinquennium than at a later age. Mr. Layton refrains from giving an opinion as to the potential infectivity of the ear discharge, and refers to the awkward position which might occur if a mastoid operation were advised at a fever hospital, because the discharge is a danger to others, rather than for the welfare of the patient. The conclusions at which he arrives in regard to treatment are not always in accordance with the practice accepted in general otological work; but it must be remembered that the management of scarlatinal otitis, especially in institutional treatment, differs from that of otorrhœa in general practice.

Paracentesis of the drum was only performed 26 times out of a total of 379 ears in which discharge occurred; this low figure is partly due to the absence of symptoms, for pain is far less frequent than in ordinary otitis, and routine inspection of the ears in the absence of symptoms is hardly practicable in large institutions; but chiefly is it due to the short period that elapses between bulging and rupture. In fact, the difficulty is to ensure the operation being carried out in time under the conditions which regulate its performance in the Board's infectious hospitals, the time necessary to obtain the consent of the parent being, in many cases, responsible for the delay. This is an administrative difficulty which would not occur in private practice and might perhaps be obviated by an alteration in the regulations; in any case, it does not detract from the value of the operation, when it can be performed, a value of which Mr. Layton is firmly convinced, though this is the one point on which his Board do not agree with him. A remarkable point is Mr. Layton's tribute to the value of Wilde's incision; this operation was performed 16 times; eight cases left the hospitals without any further operative treatment and with dry ears. Of these Mr. Layton says that "under any other plan all these children would have been submitted to the complete mastoid operation"; this remark is inaccurate, as by the "complete" is usually meant the "radical" mastoid operation, but presumably he means antrotomy, and his statement that "they would not have shown a better result" is justified. Of these eight cases one was aged 6 and one aged 5; none of the others was over 3 years old. But the other eight cases, of whom five were under 4 years of age, were later submitted to a mastoid operation; of these, one died from septicæmia and two left hospital with active disease still present. This result must be considered good; if 50 per cent. of acute otitis with retro-auricular swelling in young children can be got well with Wilde's incision, it is possible that as good results might be obtained in non-scarlatinal cases, at any rate under the age of 4 years. Surprisingly poor results are shown by antrotomy performed for ear discharge only; of six cases the first alone was a complete success; the second, operated on two months after onset, remained with a moist perforation; and the third, operated on after three months, with a discharging ear; the other three are catalogued as failures, but the date of operation is not mentioned. This is in marked contrast to the results obtained in ordinary otological practice, where operation after two or three weeks is usually successful; the date of operation is only given in these two cases, but it is possible that better results would have been obtained if they had been operated on sooner. Mr. Layton's opinion is that those cases do badly which show no signs of disease in the mastoid at operation, that it is impossible to distinguish by ordinary examination which cases have disease in the mastoid, and that an X ray examination is likely to be helpful in this respect. Accordingly he has recommended to the Board that an X ray apparatus be installed at one of the fever hospitals for examination of the mastoids of these cases, and this the Board has agreed to do at the North-Eastern Hospital.

[2] M.A.B. Annual Report. 1924–25. Pp. 187–217.

An important problem is presented by the cases discharged with active otorrhœa; there were 35 of these, of whom 17 had discharge before contracting scarlet fever. Of the remaining 18 cases, 11 had either septic scarlet fever or a mixed infection, leaving seven only of the ordinary type of scarlet fever. Surely no better tribute to the excellence of the management of these three hospitals could be desired than that only seven cases contracted an uncured scarlatinal otitis in the 13 months under review. But it is naturally desired to reduce the number still further; recognising that scarlet fever leaves the patient with a resistance profoundly lowered to the ordinary organisms of suppuration, Mr. LAYTON believes that heliotherapy should be employed, and the Board has adopted his suggestion, and proposes to set apart a ward of 12 to 20 beds for experimental sunlight treatment with an ultra-violet apparatus for use on dull days and during the winter months. Needless to say, the result of the treatment of pyogenic infections, in cases of lowered resistance, by this method will be watched by those interested in many different departments of medicine and surgery.

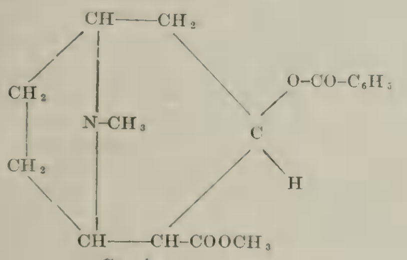
Annotations.

"Ne quid nimis."

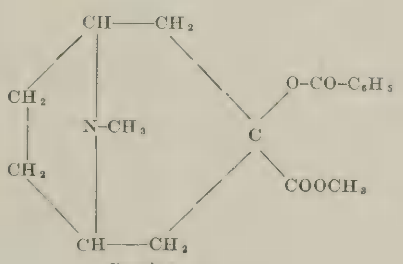
LOCAL ANÆSTHETICS AND CHEMICAL CONSTITUTION.

LOCAL anæsthetic substances have hitherto usually been employed in the form of hydrochlorides which have a definite acid reaction and are largely ionised in solution. Such solutions are fairly satisfactory in producing local anæsthesia when injected, particularly in conjunction with adrenalin, but they have little surface anæsthetic action, and on this account have not proved satisfactory substitutes for cocaine in ophthalmic surgery. For this surface action the free base appears to be far superior to the ion, and substances which undergo hydrolytic dissociation are greatly to be preferred to those undergoing electrolytic dissociation. Salts formed by combination of the base with weak acids when dissolved in water undergo very little ionic dissociation and much hydrolytic dissociation, and hence show the strong surface anæsthetic action of the base itself. At the time of the Bath meeting of the British Medical Association Dr. A. J. Copeland communicated[1] the results of experiments and tests, made by him as Ernest Hart Memorial Scholar, with the borates of these local anæsthetic bases. The work, which was carried out in conjunction with Mr. H. E. F. Notton, B.Sc., at the laboratories of pharmacology and chemistry of the University of Cambridge, is now set out at length in the *British Medical Journal* for Sept. 26th. The borates show the desired surface action in a high degree, and the local anæsthetic action of a large number of them has been measured on the cornea of the rabbit. In this way several of these borates were found to have a surface anæsthetic action equal to, and in some cases greater than, that of cocaine hydrochloride. Owing to the satisfactory results obtained with the borate of "ethocaine" (of which novocaine is the hydrochloride), special attention was paid to this substance. Not only has it a stronger surface anæsthetic action than most of the borates tested, but it also has the advantage of greater stability. It acts rapidly, both as a surface and a hypodermic anæsthetic, its surface action being more powerful than that of cocaine hydrochloride in solutions of equivalent concentration. It is practically free from any toxic action, and is non-irritant. Its solutions keep well and do not precipitate in contact with the tissues and body fluids. It is, as would be expected from the salt of a moderately strong base with a very weak acid, slightly alkaline in solution, the alkalinity of the solutions of the strength used being equivalent to pH 8. This substance, ethocaine borate, is now manufactured by the British Drug Houses, Ltd., and is available for clinical use under the name "borocaine." For convenience it is supplied in tablets together with a small quantity of adrenalin and sufficient sodium chloride and pure glucose to make an isotonic solution when dissolved in the prescribed quantity of sterile water to make a 2 per cent. solution, this being the usual strength for producing surface anæsthesia. Of the other borates that of β-eucaine is the most noteworthy, as it has the highest surface anæsthetic power of all. Further information concerning this interesting and possibly very valuable substance will be welcomed.

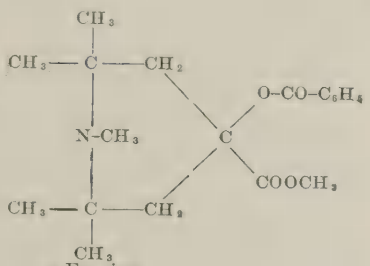
The local anæsthetics form a very interesting group from the point of view of the relation between chemical constitution and physiological action. Although the first substance to be widely used as a substitute for cocaine itself, α-eucaine has a structure somewhat resembling that of cocaine, it was soon replaced by β-eucaine, which has a structure less like that of cocaine, and subsequent developments were concerned entirely with substances, such as anæsthesine, novocaine, butyn, stovaine, tutocaine, &c., which have very little resemblance at all to cocaine from the standpoint of chemical structure. It is very curious in this connexion to note that α-cocaine resembles cocaine itself in structure far more closely than does α-eucaine, but differs from these in being quite devoid of local anæsthetic action. The more recent local anæsthetics of the ethanol, propanol, and butanol series, such as novocaine, butyn, and tutocaine, are of simpler chemical structure than cocaine, though closely related to one another, as can be seen from the structural formulæ of many of these compounds given by Mr. E. Watson-Williams in a recent account[2] of the pharmacology of tutocaine.



Cocaine.



α-Cocaine.



α-Eucaine.

EMBRYONIC DIFFERENTIATION.

THE old doctrine of preformation held that the organism was present in the germ-cell, only requiring growth and slight alteration of its parts to attain to its proper state. When it became evident that, to account for successive generations, this belief entailed the assumption that these miniature forms were contained within one another ad infinitum like Chinese boxes, the doctrine naturally fell into disfavour. It was succeeded by Wolff's theory of epigenesis, which postulated a real development or evolution from unformed matter; in its essentials correct, as a description of what takes place, founded on observed facts, but not, of course, an explanation of development. To-day we hold, in some sense, the two conceptions. We know enough of the detail of formation of an organism to recognise its epigenetic development, and at the same time we are driven to admit a more subtle form of preformation in the shape of predetermination; the organism is not there in an excessively minute but practically perfect shape, but potentially, in a form which can only reach its specific end by the long succession of epigenetic stages through which it will pass. These are basic ideas which have been and are being consolidated, while the battle has gone ahead into other regions, and concerns itself with things which were not within the horizon of the older fighters.

Embryonic development, however, is not only the expression of a prefixed potentiality showing through a series of morphological changes, but is also under the influence of interactions between these and the environment. Experiment can give us some apparently simple examples of the play of these forces. In some of the lower forms the outgrowing optic vesicle has been transplanted under the ectoderm of another part of the body, with the result that a lens has been formed in this new situation from the outer layer; evidently the power of lens formation is not a specific possession of the ordinary lens area of the ectoderm, and the power is called into action by the contiguity of the optic vesicle—i.e., by the environment. On the other hand, the optic vesicle deprived of its lens covering still invaginates to form the optic cup, thus showing that this power is inherent in it, and does not depend on the presence of the lens which, normally, occupies the hollow of the cup. Other examples of the effect of environment in the wider sense are to be seen in the well-known experiments in which the results on developing eggs of the addition of, e.g., certain salts to the surrounding media have been recorded. There is evidently predetermination, but there is also evidently in some cases a wide potentiality of development. Experiments on some of the lower animal forms have shown equipotentiality for the earlier stages of embryonic development, but other forms demonstrate, as certainly, early predetermination of parts, and in some cases, as in Driesch's experiments on the blastula of the sea-urchin, it would seem to be suggested that the localisation of special powers in one part means its removal from the rest. The cells of this blastula are at first equipotential, but, as soon as those at one pole have budded off the mesenchyme cells, they alone have the power to form the gut invagination; they cannot reform into a blastula, and the remaining cells, though they can reform into a blastula, cannot invaginate to make the gut-cavity. There has been, evidently, a rearrangement of the substances within the cells forming the blastula, and specialisation has replaced apparent non-specialisation. When such cases are considered, it is not surprising that two seemingly opposed views should be held about the nature of the developing organism. One maintains that this is fundamentally equipotential in all its parts, depending on the formative stimuli of circumstances for the result, as in the case of the lens rudiment mentioned above; the other postulates a mosaic-like arrangement of organ rudiments present from the beginning in the ovum and undergoing expansion and evolution in the processes of further development, such, indeed, having been shown to exist in certain eggs. It seems not impossible that the future will reconcile these two views and establish a via media for general purposes.

In the meantime evidence accumulates on one or other side, and among the latest contributions to the question in England is the short but very interesting account by Dr. P. D. F. Murray and Dr. J. S. Huxley, of Oxford,[1] of the self-differentiation in an experimental graft. A small basal piece of the posterior limb-bud from a four-day chick was grafted on to the chorioallantoic membrane of a seven-day incubated egg. It was removed and examined after five days. It showed a normal and well-formed femur, ossifying, with a cartilaginous patella and a small piece of pelvic cartilage, and no sign whatever of any attempt to form the distal portion of the limb. This, as the authors point out, is against the conception of equipotentiality of the tissues of the four-day limb-bud, although its structure at that time is microscopically undifferentiated. There is reason to suppose there has been regeneration of the femur in part, so that the authors suggest that it is the region that is predetermined. It would seem to follow that, within the area of the "regional mosaic," there is some amount of pluripotentiality present in the bud. In a postscript Dr. Murray and Dr. Huxley refer to more recent work by P. Weiss, who has shown that, in the newt, each segment of the limb-skeleton is totipotential as regards its own regulation, but the limb-skeleton as a whole is a mosaic of regions with different potentialities. The contribution gives a good mental picture of the uncovering of potentialities one after the other, and foreshadows a time when two conflicting views will be found to harmonise.

EXTENDED SPA TREATMENT.

IT is only by studying the figures showing the total invalidity for which insurance benefit under the National Health Insurance Act is paid that the prevalence of rheumatism amongst insured persons is really appreciated. The Special Committee investigating the incidence of rheumatism, whose report (No. 23) was published in March, 1924, found that nearly one-sixth of the total benefit paid was due to diseases classed as "rheumatic," the actual cost in 1922 being estimated at £1,000,000. Of these cases half were due to various forms of chronic arthritis. It is no wonder that the approved societies pressed for a special inquiry into the causation of rheumatism amongst the insured workers. In certain occupations the crippling forms of arthritis are more prevalent, but even there the insistence on and facilities for personal hygiene have led to some measure of control. The ætiology of these conditions will not be understood until the nature of the infection is determined, but the recent investigation clearly showed a close association with a septic focus which in so many cases is only too obvious. The proper care of the teeth and the thorough provision of dental benefit should have a great effect in reducing the incidence of these diseases, and the provision of the services of a bacteriologist and a laboratory accessible to insured persons will be a further step in the same direction. Recently the demand for spa treatment for insured persons has grown in volume, as at present it is only through charitable help that such persons can be sent to any of the treatment centres. Unfortunately, however, if assistance could be given to all the suitable cases it is certain that the present available accommodation would be quite inadequate. The special hospitals at Bath, Buxton, and Harrogate can only deal with 5000 patients each year, while statistics show that something like 370,000 insured persons seek advice for some form or other of "rheumatics" annually. Dr. Matthew B. Ray, the secretary to the British Subcommittee on Rheumatism (International Society of Medical Hydrology), has suggested that much of the treatment might be given in the workers' homes; it is not easy to instal vapour baths in an artisan's cottage, yet there is no reason why a special department should not be installed in the municipal baths. Turkish baths are, in fact, provided by certain local authorities. Sir George Newman, in his report for the year 1924, has given an admirable summary of the case for the immediate provision of treatment centres. He points out that at the present time these cases, which are not admitted into general hospitals because of their chronic nature, arrive eventually in the Poor-law infirmaries, where facilities for investigation and treatment are not adequately provided. The work of research and investigation should be undertaken at a much earlier stage in the disease, and this is only possible if cases are admitted to specially equipped institutions as soon as they are incapacitated. "Essential for research," writes Sir George Newman, "is an institution where enough cases can be concentrated in conditions to make it possible to employ a team of medical officers, where treatment and observation are systematised and represent continuous investigation." This is a great ideal, both for the medical profession and the country, an ideal which, in view of the issue at stake, should become a practical creed.

---

PROTEIN SHOCK THERAPY FOR FIBROSITIS.

A FEW years ago Dr. W. Ponndorf, of the Inoculation Institute of Weimar, set forth the claims of cutaneous inoculation of vaccines by scarification in the treatment of the "mixed infections" of tuberculosis, under which term he included almost every infectious disease to which man is prone. He prepared two vaccines: "A," which was used for pure tuberculosis, consisted of concentrated Koch's Old Tuberculin with the addition of an empirically determined amount of human and bovine autolysed tubercle bacilli; "B," for the mixed infections, was similar to "A," plus the endotoxins of streptococci, staphylococci, pneumococci, and influenza bacilli. Inspired by the effect which Ponndorf's vaccines seemed to have on rheumatic conditions, Dr. Gustav Paul, director of the State Inoculation Institute of Vienna, began some four years ago to test the clinical value of that method of treatment, and in a recent issue of the *Wiener Klinische Wochenschrift* (Sept. 3rd, p. 984) he records his results in nearly 600 cases of rheumatism where he administered vaccine by scarification.

The ætiology and history of Dr. Paul's enthusiasm for the treatment is not without interest. The story, as he himself tells it, is as follows. Although he had been familiar with Ponndorf's theories for many years, he had never tested them in practice owing to lack of suitable material. As a result of a visit to Weimar in 1921, however, he was so impressed with the possibilities of Ponndorf's claims that he obtained facilities to carry out this method of inoculation in the sanatorium for children suffering from surgical tuberculosis in Grimmstein, Lower Austria. In addition to over 300 cases of tuberculosis of the bones and glands in children, in which the treatment proved satisfactory, Dr. Paul was able to observe what he terms the "amazing" (*verblüffend*) curative powers of the vaccine in some 50 adults, nurses, and officials of the sanatorium, who suffered from rheumatism. In 1923 the Grimmstein sanatorium was closed down, and as Dr. Paul had no private practice of his own wherewith to continue his observations, he feared that further investigation on his part might lapse. Fortune favoured him, however, and the successful treatment of a "lady of quality" in Austria formed the nucleus of a private clinic for ambulatory cases of rheumatism, which up to the present has furnished him with some 600 cases. Dr. Paul does not describe his technique in detail, but indicates that a small area of skin is scarified, without drawing blood, and then the vaccine is applied in a carefully regulated dosage, which depends on the size of the field of inoculation, the number of scarifications, and the amount of the vaccine. The superiority of his method over the more usual methods of protein shock he ascribes to: (1) the happy combination of toxin and bacterial protein; (2) the manner in which they are assimilated; and (3) the correct choice of absorption routes—which should be by the lymphatics. The first application of the vaccine serves to sensitise the patient, and the subsequent allergy and local reaction furnishes a valuable indication in estimating the amount of individual tolerance. The results Dr. Paul has obtained in his completed cases are reproduced in the following table:—

Condition.	Case-incidence.	Cured.	Considerably improved.	Unchanged	Worse.
Arthritis deformans . .	35	11	18	4	2
Chronic rheumatoid arthritis	147	95	48	3	1
Arthritis of shoulder-joint	35	27	7	1	—
Muscular rheumatism	26	19	6	1	—
Sciatica	44	34	9	1	—
Chronic lumbago . .	23	15	8	—	—
Neuralgias	32	19	9	4	—
Total	342	220	105	14	3

He has thus 65 per cent. of cures and 95 per cent. of improvements to record, and in a further series of 257 uncompleted cases improvement already reached 75 per cent. Dr. Paul points out that these high percentages are all the more noteworthy as the majority of cases classified as chronic rheumatoid arthritis represented transition stages towards arthritis deformans, and further, most of these patients had come to him as a last resort, having been previously treated unsuccessfully by every other known therapeutic agent. He attributes the failure of other methods, such as balneo-therapy, drug treatment, and radiation, to the over-energetic and heroic manner in which they are exhibited, quoting Prof. Bier's views on the over-sensitive state of the chronically inflamed tissues which require the smallest possible stimulus to promote the activity of the cell.

Dr. Paul's method, therefore, falls into the category of non-specific protein shock therapy, in which the touchstone is not "quale" but "quantum"; and he regards the effective substitution of some other antigen for Ponndorf's tuberculin as within the bounds of possibility, "for," as he says, "the medical world is somewhat tuberculin-weary." His claims are very large and in view of the official position he holds are hardly likely to pass unnoticed. They should certainly be tested by those who are dissatisfied with their own results in the big group of fibrositic maladies.

PROF. RICHET'S RETIREMENT.

THE retirement of Charles Richet from the chair of physiology in the Paris Faculty of Medicine, after 47 years of devoted teaching and brilliant research, recalls to mind the enormous strides made in his subject during the span of his professional life. Fifty years ago the renaissance of physiology was but just beginning and the young Richet was the pupil of such masters as Berthelot, Marey, Vulpian, and Claude Bernard. The field was ripe to the harvest, and Richet and his contemporaries piled discovery on discovery, and what to them were new facts wrung from Nature by hours of patient research are to us almost banal. The diuretic properties of sugar, for instance, the refractory period of the nervous system, the salt-free diet for epilepsy, the virtues of chloralose, the influence of anæsthesia on respiration—with all these points the name of Prof. Richet is associated, as well as first and foremost with the discovery of anaphylaxis. In his recent farewell address [1] to the Faculty, the aged professor reviewed the work of the physiological laboratory since 1881 with particular reference to five of his most significant lines of research.

The essential principles of temperature regulation were first explained by Prof. Richet in 1884, an almost accidental result of some experiments on electrically produced pyrexia in dogs. The rapid breathing of the dog in hot sunshine was called by him "polypnœa" in recognition of the fact that it was no laboured panting or "thermal dyspnœa" as older physiologists called it, but an evaporation process whereby the temperature of the animal's body was kept level in extremes of environmental heat, just as the human being is kept cool by evaporation of sweat from the naked surface. A muzzled dog, to whom this protection was forbidden, would die of heat in half an hour. Prof. Richet also demonstrated that two mechanisms regulate this thermal polypnœa, a reflex and a central. The reflex panting or sweating stimulated by simple contact with warm air prevents rise of temperature; when it is inhibited by an anæsthetic, such as chloral, the blood temperature may go as high as 108·5° F. before its heat stimulates the bulbar centres and panting or sweating is initiated centrally so that the temperature falls. The parallel mechanism of shivering to prevent loss of heat from the body was shown to require a temperature of 93° before the central stimulation occurred. The application of these physiological facts to the clinical phenomena of fever has revolutionised our attitude to temperature states. Perhaps most epoch-making of all the work emanating from the Paris laboratory was that on serotherapy, which began with some speculative remarks in a lecture delivered by Prof. Richet in 1883. Commenting on the comparative immunity to anthrax of Algerian sheep and the susceptibility of French breeds, he suggested that injection of Algerian blood might confer immunity on French animals. Some years later the well-known experiments on *Staphylococcus pyosepticus* were carried out, in collaboration with Prof. Héricourt, and in 1888 it was established that the blood of an immunised animal will confer immunity on one that was previously susceptible. Their further researches led them along a road of which the end is not yet in sight—the search for a satisfactory serum for tuberculosis. Their principle has been amply corroborated by contemporary and later workers, who followed the more promising lines of diphtheria and tetanus. A clinical offshoot of the tuberculosis experiments was the discovery of the virtue of raw meat-juice in this disease. Its value is admittedly restricted to early cases, but Prof. Richet claims that the administration of the correct quantities—somewhat large ones—is followed by a gain in weight and strength and an increase of azote and phosphoric acid in the urine. Genetics received a contribution from the researches of Richet and H. Cardot into lactic fermentation, out of which arose the discovery that micro-organisms cultivated in certain media acquire new characteristics and transmit them to their offspring. Anaphylaxis is one of the most unexpected of all physiological phenomena, and the original researches of Prof. Richet and Dr. Paul Portier into this subject arose from an unexpected and piquant direction. It was while accompanying one of the deep-sea expeditions of Prince Albert of Monaco that their experiments with poisonous actinia revealed this phenomenon. To their profound surprise dogs that had recovered from a sublethal dose succumbed in two minutes to a trifling second injection.

Prof. Richet's career is one of which his countrymen and fellow-workers may well feel proud. Like all great discoverers he confesses the debt he owes to happy chance, but he adds, as every worker knows to be true, that that good luck must be the benison of the gods on labour, on faith in science, on enthusiasm for research. It is because he has passionately loved physiology that he has rendered to it and to the world such fruitful service. He passes into retirement full of years and honour, and accompanied by the cordial good wishes of scientists and medical men in every part of the world.

THE MEASUREMENT OF ATMOSPHERIC DUST.

THE importance of atmospheric dust as a cause of respiratory disease has long been recognised. Certain forms, such as coal-dust, flour, and dust from grain elevators may be so finely divided as to become highly explosive in suitable concentration; whilst it has long been known that dust plays a part in the condensation of water from the atmosphere to form clouds and fog. These facts make it necessary to have some means of measuring dust, and many have been devised. The well-known method utilised by John Aitken [1] depends on the condensation of water vapour on the suspended particles, by which only the hygroscopic nuclei are taken into account and the rest are neglected. Another principle was brought into service in an instrument devised by Dr. J. S. Owens three or four years ago for the Advisory Committee on Atmospheric Pollution. The air to be examined is caused to impinge at high velocity upon a microscope cover-glass, the jet being ribbon-shaped and the velocity of impact approximately that of sound; the jet is formed by an air-pump of 50 c.cm. capacity, which serves thus to measure the volume, and the reduction in pressure brought about in the jet causes condensation of water upon such particles as have an affinity for it. With their load of water, these impinge upon the cover-glass wetting the point of impact and thus causing all particles which strike the glass to adhere. The air approaches the jet through a chamber with damp walls to assure the presence of sufficient vapour to bring about adhesion of the dust. The record thus obtained is mounted for microscopic examination and counted under a 1/12 in. oil-immersion objective with the aid of a micrometer eye-piece. This instrument takes account of all dust particles, whether hygroscopic or not. In the "konimeter" devised by Sir R. N. Kotze for the Miners' Phthisis Prevention Committee of South Africa (1916) and since used extensively for the examination of silicious mine dust, a round jet of air is caused to strike a glass plate on which vaseline is smeared and the particles which adhere are counted. There are, in fact, many methods and it is hard to estimate their relative efficiency. A bulletin [2] just published by the United States Public Health Service, describes some comparative tests. The efficiency of six different instruments was compared for dust produced artificially from iron, grain, silica, coal, and limestone, and was determined by an ingenious application of the Tyndall beam method. Two jets of air, one of which had passed through the instrument to be tested and one of which had not, were viewed side by side against a black background under brilliant illumination. The dust-laden air was diluted with measured amounts of dust-free air until the two streams matched each other in intensity of reflected light, and the amount of dilution required provided a measure of the efficiency. The instruments tested were the sugar tube, in which air is drawn through a filter of fine sugar, subsequently dissolved, and the trapped impurity separated for weighing, or counted in the solution; the Palmer apparatus in which the air is automatically agitated with water spray in a special glass bulb, the resulting suspension being examined gravimetrically or by microscopical counting; the konimeter above referred to; the paper thimble, a little cup of filter-paper used to filter the dust out of a measured volume of the air for subsequent weighing; and the dust determinator, an instrument in which the air is drawn through a filter-paper disc and the quantity of dust estimated from the variation of resistance to flow as the pores become choked with dust. This last instrument could not be compared with the others, its results being in terms of resistance to air-flow. The sixth instrument, called an impinger tube, consists of a tube entering a small flask of about 500 c.cm. capacity and containing about 200 c.cm. of water. The tube ends in a number of small orifices under the surface of the water, whilst at a distance of a few millimetres from these orifices a plate is fixed against which the jets impinge. The air is caused to flow from these orifices by means of an aspirator. There was a great variation in the results obtained by the different methods. Three selected examples of such variation are given, the figures being in dust particles per cubic centimetre for the same air :—

[1] Collected Scientific Papers (Cambridge, 1923).

[2] Comparative Tests of Instruments for Determining Atmospheric Dusts. Public Health Bulletin, No. 144, Treasury Department. United States Public Health Service. Washington. 1925.

	Iron dust.	Silica.	Coal.
Sugar tube	3,798	5,791	519
Palmer apparatus	7,107	3,310	541
Konimeter	2,269	1,417	1079
Impinger	22,811	11,532	1167

The investigation related mainly to dense dusts such as are liable to cause explosions and was not concerned with the smaller and less concentrated particles found in the open air. The Palmer apparatus was considered useful for insoluble dusts, but its efficiency is stated to be low. The konimeter was found to be impossible to use when the dustiness exceeded 600 to 800 particles per cubic centimetre, and this conclusion is supported by investigations by Dr. Owens, in whose experience the use of an adhesive in such instruments makes high efficiency impossible. Impact methods require a very high velocity jet, and if an adhesive is used it is blown away from the point of impact.

THE VALUE OF LUMINAL.

THE number and diversity of the measures that have been advocated in the treatment of epilepsy are a pretty good indication of their ineffectiveness. Psycho-analysis is now ranged with cerebral surgery as of value only in a small group of cases. Good general hygiene and appropriate environment are of great importance but often difficult of attainment. Most practitioners, faced with cases of epilepsy, are chiefly interested in the control of the seizures by medicines. Have any of the new remedies established themselves sufficiently to be worth a trial ? Or does bromine, in one form or another, hold the field to the exclusion of everything else ? The answer is not a simple one. The good old remedies, borax and belladonna, still have their place. Borax would appear to lessen the number of fits, but rarely to arrest them ; while belladonna may give brilliant results in a special group of cases. Peptone therapy, endocrines of various sorts, colloidal palladium are on their trial ; it looks as if the verdict is not to be favourable. But in luminal we seem to possess a valuable weapon. In Germany, America, France, and this country much has been published about its use in epilepsy. The evidence is considerable, but more should be made available. For this reason we welcome the publication by the Metropolitan Asylums Board of the collected experience of its use in four of their institutions, the drug having been given for periods of three months and upwards, in doses of from 1–4 gr. daily, to nearly 200 patients.[1] The results, like those of other observers, have been diverse, but a study of the fit-incidence leaves no doubt that the drug is well worthy of a trial. Nor is its benefit confined to fit-reduction ; improvement in the associated mental state is also noted in many cases. It must be remembered that all, or nearly all, of the patients in this series were certified mental defectives, and it is probable that the recorded results on a similar number of what may be called normal epileptics would be a good deal more encouraging. The answer to the question as to which cases are likely to benefit by luminal is not yet forthcoming. There is a general consensus of opinion that it is most useful when the fits are of the major type and where the disease has only shown itself recently. Dr. O. G. Misquith's experience (see p. 728) is typical in this respect. But much the same is true of bromide or any other drug that reduces fit-incidence. Certain general observations may now be made about the use of luminal. It is of no value in hysterical fits. In cases of epilepsy, tolerance is apt to occur, so that the results in the first three months of luminal treatment may be the best. An alarming increase of fits may occur on withdrawal of the drug which should therefore be gradually effected and carefully watched. Where luminal arrests the fits, especially in children, there may be a change in mental character ; irritability has often been noticed, sometimes of a high degree. Even with small doses, rather formidable morbilliform or scarlatiniform rashes have occasionally appeared. Other toxic symptoms do not occur, unless the dose given be larger than that mentioned. But above this, as Dr. S. Grossman pointed out last week, stupor and restlessness may soon be the result. Outside a resident institution the practitioner will be well advised to make 3-4 gr. the maximum for 24 hours, and not be tempted to increase it if this amount seems to lose its effect. The alarming result of giving (inadvertently) 10 gr. daily for 12 days was set out by Dr. Hildred Carlill in an interesting clinical note a fortnight ago.

ACTIVE IMMUNISATION AGAINST DIPHTHERIA.

LAST autumn our Vienna correspondent described [1] an outbreak of diphtheria in a home for infants and young children at Baden, near Vienna, where as a precautionary measure active immunisation was carried out with a 20 per cent. toxin-antitoxin mixture in about 40 children. Six of these children promptly died with typical local and general symptoms of diphtheritic intoxication, and several others showed areas of skin necrosis of various sizes. The mixture had been tested before being issued on guinea-pigs and had been found non-toxic, and the suggestion offered for its subsequent toxicity was that a dissociation of the toxin and antitoxin had taken place. The cause of this dissociation was not forthcoming. There did not appear, however, to have been any question of accidental freezing of the mixture as in the cases reported in Massachusetts earlier in the same year.[2] Under the circumstances the Austrian Ministry of Health referred the matter to Prof. Pirquet for further inquiry, and in a recent article [3] Dr. E. Helmreich, assistant to Prof. Pirquet, discusses the present position in Austria of active immunisation against diphtheria. During the last 15 years diphtheria in Austria has, it appears, assumed so mild a form that no energetic measures have been taken for dealing with it. Prof. Pirquet himself maintains that the immunity conferred by toxin-antitoxin lasts at most a few years and certainly does not persist throughout life. He is therefore in favour of continuing the method of immunisation which has been practised in the Vienna University Children's Clinic for the last few years in lieu of toxin-antitoxin—viz., careful clinical examination of children exposed to diphtheria, immediate injection with antitoxin of those presenting symptoms suggestive of diphtheria, and Schick testing the rest. Those who gave a negative reaction required no further attention, while those with a positive reaction received 500 units of antitoxin. Should a severe epidemic occur, or new facts be brought to light showing that an absolutely harmless toxin-antitoxin mixture could be supplied, the matter might be reopened. In the meantime he proposed that active immunisation against diphtheria by toxin-antitoxin should be discontinued. Prof. Pirquet's proposal was adopted by the Austrian Ministry of Health, and the performance of active immunisation is now forbidden in Austria. Unfortunately we are still in the dark as to origin of the Vienna tragedy, which has had no parallel in other countries where the use of toxin-antitoxin mixture as a prophylactic is on the increase. We hope that the Austrian authorities will insist on tracing the accident to its source with a view to its avoidance in future rather than simply prohibit one of the most promising avenues of preventive medicine.

WHAT CONSTITUTES A CURE IN PSYCHOTHERAPY?

There is an urgent need for some definite standard of " cure " in psychotherapy, if this form of treatment is to take its place with the established therapeutic procedures. Psychotherapists are divided into several schools and the symptoms grouped under the vague term " neurosis " are very elusive, so that the criterion of cure is much more difficult to determine than in organic disease. Dr. Otto Veraguth has collected[1] definitions of cure from a number of leading psychotherapists. Freud says briefly, " a cure is the restoration of productive ability and the capacity for enjoyment." Stekel defines it as, " the conquest by the neurotic of his tendency to isolation, a regained capacity for work and sexual activity, and abandonment of phantasy in favour of reality." Jung claims that his method produces " a maturity of character, due to conscious understanding and assimilation of the undeveloped parts of the personality enabling the patient to adapt himself to the claims of life which he had hitherto—wittingly or unwittingly—failed to face." Frank distinguishes between a " scientific " cure and a " practical and social " cure. In practice, a cure is claimed when pathological symptoms are no longer seen, although this may be only the result of improved environmental conditions. Bezzola regards a cure as the removal of the bad suggestions induced by education, environment, and psychic trauma, so that the individual is free to educate himself. Maeder distinguishes between the strictly medical and the pedagogic attitude towards the patient. The latter includes, as well as removal of symptoms and restoration of ability, the synthesis of the personality and the integration of the individual as a member of the cosmos. Dr. Veraguth points out that the drive of life may be divided into four main branches from a common stem: The preservation and development, respectively, of the individual and of the species. The drive towards individual evolution, towards differentiation and progress, has received inadequate recognition, but its existence is self-evident. When its activity is limited to somatic processes the individual is an uneducable idiot, but its presence in normal men is reflected in the peculiar plasticity of the human brain; such characters as Faust or the hermit show instances of men whose flow of life energy is disproportionately strong along this channel. The drive towards development of the species expresses itself psychically in the higher forms of affectivity; the man in whom it is excessively energised is the prophet. In the healthy man the four principles should be evenly balanced within the limits of individual and age variation; in the neurotic there is, or has been in the past, a lack of this balance. Dr. Veraguth's definition of psychotherapeutic cure is the restoration of the balance, and he goes on to discuss how it is manifested. The objective signs are the permanence of the result achieved and the freeing of the patient from dependence on his doctor. He quotes a number of cases to show the caution that must be exercised in estimating these signs. " Permanence " must take into consideration the cyclical fluctuation of manic-depressive types; the passage from one psychic phase to another may easily give a false impression of cure. Renewed ability to work must only be taken as a criterion of cure when judged both qualitatively and quantitatively. Renewed capacity for enjoyment must include all aspects of life: the preponderance of sexual difficulties among psychotherapeutic patients has misled some practitioners into regarding restored enjoyment of this function as a sign of cure. Freedom from the doctor's influence must not be confused with a negative transference which is a sign that cure has not been effected. More important, however, than these, in Dr. Veraguth's opinion, is the subjective conviction of the erstwhile patient that his personality has grown, a feeling not of ability to work, but of self-application to work; not of capacity for enjoyment, but of determination to enjoy; not of adaptation to the demands of life, but of a personal choice between adaptation and resistance. A further and peculiar sign of cure is the sense of gratitude for his former symptoms. The patient finds that he has been cured of so much more than he originally complained of that he can rejoice in his former tribulations, since they led him to the treatment that opened up to him new fields of life. Dr. Veraguth ends with a plea, which we cordially endorse, for the publication by experienced psychotherapists of quantitative statistics.

FOULING OF FOOTWAYS BY DOGS.

In the Royal Borough of Kensington there are many flats and maisonettes to which no gardens are attached, with the result that dogs are exercised on the footways. Owing to the fouling of the footways as a result of this practice, the borough council in 1921 obtained the sanction of the Home Secretary to the following by-law:—

> " No person being in charge of a dog in any street or public place and having the dog on a lead shall allow or permit the dog to deposit its excrement upon the public footway.
>
> " Any person offending against this by-law shall be liable to a penalty not exceeding 40*s*."

The by-law was made in pursuance of Section 23 of the Municipal Corporations Act, 1882, Section 16 of the Local Government Act, 1888, and Section 5 of the Local Government Act, 1899, for the good rule and government of the Royal borough. Two officers of the public health department report breaches of the by-law detected by them to the Health Committee. These officers are engaged on other outdoor duties and make their observations whilst passing from place to place in the borough. A leaflet calling attention to the requirements of the by-law has been delivered to a large number of dog owners, a poster in similar terms has been exhibited in the borough, and a printed slip has been attached to the rate demand notices. During 1922 two offences were reported to the Public Health Committee and a warning was issued in each case. In 1923 two warnings were issued and in the case of a third offence a summons was taken out, the defendant being fined 5*s*. In 1924 a conviction was obtained in each of the four summonses issued; in one case the fine was 5*s*. and in each of the other three 10*s*. Dr. James Fenton, borough medical officer of health, tells us that the condition of the footways in the borough has improved very considerably since the by-law came into operation, and that several other boroughs have adopted a similar measure. As Dr. Andrew Balfour has pointed out,[1] the traffic in London streets is now such that the dog can no longer use the roadway for his calls of nature and is obliged for purposes of safety and comfort to resort to the sidewalk. Mr. T. W. M. Cameron, M.R.C.V.S., of Edinburgh, has discussed[2] the dog as a carrier of disease to man, mentioning several roundworms and cestodes which might come into question apart from the dangerous hydatid. The Wellcome Bureau of Scientific Research examined numerous samples of excreta, presumed to be those of the dog, on London pavements in the neighbourhood

of Gordon-square. Eggs of helminths were found in a small proportion of cases, the type being that of ascaris in 3 per cent., of *Tænia serrata* in 2, and of ankylostoma in 1. In nearly 5 per cent. cysts of giardia were found and a new coccidium of the dog was discovered. The inquiry revealed no evidence of hydatid disease, and Dr. Balfour then expressed the opinion that the presence of dog excrement, however offensive on æsthetic grounds, was not to be regarded as disquieting from the point of view of public health. He admitted, however, that apart from the work of the Wellcome Bureau little, if anything, seemed to be known as to the dangers which might lurk in the fæces of dogs.

A CHANCE FOR THE AMATEUR PHILOSOPHER.

It is supposed that philosophers can retire at will to some higher world where the air is so rarefied that they are undisturbed by the presence of the populace and where everything is so vague that it cannot be offensive. There are none who would find the gift of voluntary translation more useful or more enjoyable than members of the medical profession; but without long practice it is impossible to live in the atmospheric conditions of the abstract world. The novice only too frequently can be heard puffing and blowing in the air just above our heads, and though he may see more than the rest he appears uncomfortable and inadequately balanced. There is, however, a certain number of professionals (so to speak) who are willing to descend from their pinnacles and prescribe suitable exercises which are helpful without being ridiculous. Though nobody imbued with the scientific spirit willingly believes authorities, they can at least show the way by which they got to where they are; and no man can do more. The British Institute of Philosophical Studies is willing to arrange such assistance, and it suggests that certain courses of lectures would be particularly helpful to the medical man who comes back perforce to his material patients from time to time. During the next sessions there will be lectures by Prof. T. H. Pear on Psychology, by Prof. James Johnstone on Life and Mind, and by Prof. Leonard Russell on the Conception of Matter, and each of these is calculated to be of great interest to doctors. The Institute, which is under the presidency of Lord Balfour, will provide courses of lectures on the more important subjects coming within the scope of philosophy; will arrange classes under tutorial guidance; will give assistance to individuals in their reading and encourage research in philosophy, and will form a library. The temporary office is at 88, Kingsway, London, W.C., and it is to be hoped that members of the profession will avail themselves freely of the admirable facilities provided by the Institute. Details of the times and places of the lectures will be found on reference to our advertisement columns.

THE MOTOR EXHIBITION, 1925.

The annual motor exhibition at Olympia, organised by the Society of Motor Manufacturers and Traders, Ltd., in connexion with the Royal Automobile Club, will be held from Oct. 9th to 17th. This great exhibition, which has always been international in character, promises this year to be one of the largest assemblies of everything pertaining to motor-cars that has ever been gathered under one roof, and additional importance attaches to the show as the Paris motor exhibition will not be held this autumn. Whatever gloomy views may be taken of certain British trades and industries, one can hardly feel despondent about the manufacture of motor-cars and their accessories, and in the last four years the number of motor vehicles registered in this country has increased by over 100,000 annually. On the one hand, the market for cars has greatly widened its boundaries, the difficulties attending mass production methods have been largely eliminated, and improved plant has increased output; on the other hand, labour is more costly, taxation heavier, and expenses higher, but nevertheless the balance is on the right side and car value to-day has never been approached at any period of the industry. The car that appeals to the average medical man may be said to be that of the £300 to £400 class, and it is in this class that the keenest competition on the part of the manufacturers has resulted in the maximum advantage to the purchaser. Although no revolution in price, design, or construction is foreshadowed, the process of evolution will be in evidence, not the least in these apparently minor details the perfection of which makes for the difference between owning a car and being owned by it. The exhibition will remain open daily from 10 A.M. to 10 P.M.

Summer-time in Great Britain ends at 3 A.M. on Sunday, Oct. 4th, when the clock will be put back to 2 A.M. In France the return to normal time takes place on Oct. 4th at midnight (zero hour), the change therefore being practically simultaneous on the two sides of the Channel. Belgium follows the French practice.

Some idea of the admirable work done in Iraq during the past two years may be gained from the abstract of the report of the Director-General of Health Services, which appears on p. 733. Reversion to the "simplified" hygiene of purely Eastern government would be especially disastrous since railways and motors have opened up the country to the ravages of epidemics. It would be most regrettable if the British officers in the service should have to cease work before they can build up a local organisation whose members are ready and willing to do the personal work amongst the tribes which is so urgently needed in this disease-ridden country.

The first social evening of the new session of the Royal Society of Medicine will be held on Tuesday, Oct. 27th, at 8.30 P.M., when Fellows and their guests will be received by the President, Sir StClair Thomson, who, at 9.30 P.M. will give a short address on "Shakespeare as a Guide in the Art and Practice of Medicine." The library will be open, and there will be an exhibition of the drugs which are mentioned in Shakespeare's plays; the display will be lent by the Wellcome Historical Medical Museum and arranged by Mr. C. J. S. Thompson, the curator.

Society of Superintendents of Tuberculosis Institutions.—It has been impossible to arrange to hold the proposed Provincial Meeting of this Society at Leeds. The ordinary meeting will be held in London in October. The exact date will be announced later.

Fellowship of Medicine and Post-Graduate Medical Association.—A series of lectures on Tuberculosis will be held in the Lecture-room of the Medical Society, 11, Chandos-street, during October, November, and December. The first lecture will be given on Oct. 12th at 5.30 P.M. by Dr. L. S. Burrell, on Tuberculosis from the Physician's Viewpoint. There is no fee for attendance at this series, and all members of the medical profession will be welcomed. On Monday, Oct. 5th, the Central London Throat, Nose and Ear Hospital will begin a three weeks' course in Laryngology, Rhinology, and Otology. The clinical course will be from about 9 A.M. to 5 P.M. daily, and an operative surgery class will also be held. The operative surgery and the clinical classes may be taken together or singly. The London School of Hygiene and Tropical Medicine have the first two of their series of eight clinical demonstrations on Tuesday, Oct. 6th, and Thursday, Oct. 8th, at 2 P.M. Dr. G. C. Low and Dr. P. Manson-Bahr will consider the more important diseases of tropical countries. Other courses in October will commence as follows: Oct. 12th, a combined course in Children's Diseases at the Paddington Green Hospital, Victoria Hospital for Children, and Children's Clinic; Oct. 19th, a course in Urology at St. Peter's Hospital; Oct. 26th, a course in Dermatology at St. John's Hospital. Copies of any syllabus, together with the Fellowship programme, may be obtained from the Secretary, 1, Wimpole-street, London, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXLI.—THE TREATMENT OF VISCEROPTOSIS.

A diagnosis of visceroptosis is one which it is only too easy to make on insufficient evidence, and which is only too readily accepted by the patient. To the lay mind the fact that the viscera are dropped or misplaced offers a reasonable explanation to account for symptoms of any and every kind; moreover, it is an idea which it is much easier to implant than to eradicate from the mind of the patient. Hence, it is most important to beware of informing patients that they have visceroptosis, whether general or of special organs such as the kidney, unless the clinical condition is explicable on no other pathological basis; further, when such a diagnosis is made it must be explained clearly that the condition is not a serious one and is readily amenable to treatment.

Possible Organic Lesions.

Before attempting any treatment for visceroptosis the possibility of other organic lesions such as peptic ulcer must be excluded as far as possible, and the diagnosis should never be made apart from radiographic evidence. Even when the latter appears to support the diagnosis, it must be remembered that many individuals who are apparently in perfect health can be shown to have considerable ptosis of such organs as the stomach or colon. In fact, the position of the viscera depends largely on the habitus or general bodily configuration of the patient. Individuals with a long chest and narrow intercostal angle almost invariably have their viscera considerably lower than the broad-chested type with a wide intercostal angle.

The viscera are retained in their normal positions by the abdominal muscles, which maintain a positive intra-abdominal pressure, rather than by the support of the various mesenteries and peritoneal ligaments. Hence, in the treatment of visceroptosis it is to the abdominal muscles that attention must be paid. In this disease, as in all others, prevention is better than cure. Perhaps the most common cause of visceroptosis as a clinical syndrome is pregnancy or particularly a series of pregnancies at relatively short intervals. When the uterus is emptied and contracts down within a few days from a large abdominal tumour to a small pelvic organ, the intra-abdominal pressure is much decreased, and if the patient is allowed to get up too early the abdominal muscles, which have long been on the stretch, are unable to maintain themselves in a sufficient degree of tonus to counteract the tendency of the abdominal viscera to drop downwards and forwards. Hence, in the prophylaxis of visceroptosis it is most important to insist on a patient after delivery remaining in bed or at least recumbent for a fortnight or longer if the abdominal wall is thin or if pregnancies have been frequent.

Restoration of Tone in Abdominal Muscles.

The ultimate cure of visceroptosis is dependent on the restoration of tone in the abdominal muscles, and it is therefore to this end that treatment must be directed. In too many cases abdominal massage is the sole method employed. Though massage may have its uses, particularly in the cases in which constipation is a marked feature, as far as the development of the abdominal musculature is concerned, it is vastly inferior to active movements. The patient should be given a series of exercises designed to bring these muscles into play; in severe and long-standing cases at the beginning the exercises will have to be comparatively light in character, but as the condition improves they can be increased in duration and severity. Where it is possible the patient should be placed under the charge of an expert in remedial exercises; moreover, it is always more satisfactory if these can be done in a class rather than individually, as the presence of other patients in a class tends to produce a competitive spirit and renders the maintenance of discipline more easy. It is impossible in the compass of these notes to describe the exercises in detail; in general, it may be said that they should consist mainly of active movements by the abdominal muscles and the diaphragm, which in most visceroptotic patients is unduly low with a restricted respiratory excursion. Breathing exercises are carried out lying on the back with the legs drawn up and the thorax partially fixed by the arms folded over the chest; the breathing is thus rendered mainly diaphragmatic in type. The recti muscles are exercised by raising the head and neck with the patient on the back and by flexion and extension of the hips with the patient in the same position. It is most important that the patient should be closely supervised especially in the earlier part of the training, in order to ensure that the movements are being carried out correctly and that they are not beyond the patient's strength. Moreover, in addition to the regular exercises done under supervision the importance of carrying out the treatment daily in the home must be impressed on the patient.

Constipation.

One of the most constant and troublesome symptoms in visceroptosis is obstinate constipation. In most cases this is due originally to the lax abdominal muscles having insufficient power to produce a complete evacuation. As a secondary result of this a condition of dyschezia results, in which the rectum becomes insensitive to distension with fæcal material. For the cure of the constipation it is essential that the patient should be re-educated in defæcation; it must be insisted that at a fixed hour after breakfast an attempt should be made to obtain a movement, and that the use of strong purgatives should be discontinued. At the beginning of treatment a daily soap-and-water enema may be necessary, but this should be gradually diminished in bulk from day to day. Massage of the colon is also useful in the treatment, and where possible this should to begin with be carried out by the masseuse with the patient on an X ray couch after a barium meal has been taken on the previous day to outline the large intestine; the masseuse is thus able to be sure of the exact position of the colon. If this procedure is not feasible the masseuse should be provided with a sketch or X ray photograph showing the outline of the colon.

Abdominal Support.

In severe cases an abdominal belt should be worn. This may be either of elastic and webbing material, or a leather and metal instrument such as the Curtis abdominal support. Although the latter is heavier and less comfortable to wear it gives better support and is free from the liability of the elastic type to stretch unduly. In either case the belt must be so adjusted that the direction of pressure must be upwards and backwards. It need not be worn when the patient is in bed or lying down, and when it is being applied the patient must invariably be in a recumbent position with the pelvis raised, as otherwise there is a grave risk of its tending to hold the viscera down rather than up. In cases where a belt is ordered the physician must be careful to explain to the patient that it is not in itself a cure and must not be made an excuse to discontinue the exercise treatment, which should be carried out with the belt removed.

In all true cases of visceroptosis all the organs, rather than a single one such as the stomach, colon, or kidney, are ptosed. Consequently, attempts to deal with individual organs are doomed to failure, though in some cases the most distressing symptoms are occasionally attributable to one particular organ, especially the kidney. In rare cases undue mobility of the latter may lead to severe attacks resembling renal colic, but where these so-called Dietl's crises occur there is often an aberrant renal vessel which obstructs the ureter. In the vast majority of cases with nephroptosis any attempt at nephropexy only aggravates the condition. As a general rule surgery should never be advised unless there is undoubted evidence of ureteric obstruction.

Diet.

As regards diet, patients with visceroptosis are, as a rule, thin and should be encouraged to take a nourishing mixed diet of small bulk. As an intestinal lubricant to enable the fæces to be more readily expelled liquid paraffin is most invaluable and should be taken in small amounts at least twice a day. In cases with marked gastroptosis the patient should be instructed to lie down on the right side for half an hour after meals, as this tends to accelerate the passage of food from the stomach into the intestines.

In very severe cases with marked laxity of the abdominal wall the patient may be kept in bed for some weeks, the foot of the bed being supported on blocks. This takes the tension off the stretched abdominal muscles and allows them to some extent to recover their tone.

The Mental State.

Patients with visceroptosis are usually highly neurotic and often their main occupation in life becomes the minute observance and recording of their symptoms. This aspect of the case is often the most difficult to deal with, and quite apart from other considerations makes any operative treatment extremely undesirable. An attempt must be made to gain the patient's confidence and, if possible, to alter the general mental outlook. Naturally, the most difficult cases are those where the attention of the patient has been focused on some particular organ, such as the kidney, by the ill-judged remarks of the medical attendant.

PUBLIC HEALTH ADMINISTRATION.

ADMINISTRATIVE MACHINERY IN EUROPEAN COUNTRIES.*

(*Continued from p. 653.*)

IV. GERMANY.

THE German Reich (realm) is a national entity formed by the federation of 18 States, which, so long and in so far as the Reich does not use its legislative power, possess the right of enacting their own laws. Under various Articles of the Constitution of August 11th, 1919, the Reich has legislative authority in regard to matters affecting the population, the care of mothers, nurslings, children and the young, and health. The Reich Government supervises the execution of Reich laws by the authorities of the various States of which it is composed.

Questions of health affecting the Reich are dealt with mainly by the Reich Ministry of the Interior and the Reich Ministry of Labour. Department II. in the former conducts all business connected with public health, including medical staff, medical examinations and preventive measures against diseases, attempts to procure abortion, infantile mortality, tuberculosis, and the abuse of alcohol and tobacco; the supervision of public food, the advanced training of doctors, pharmacies, the foodstuffs trade, veterinary surgery, and, to a certain extent, industrial hygiene and poor relief come under this department. A special sub-department is directed by a medical counsellor in the Ministry, and two medical secretaries are employed. Department III. deals with education, child welfare, physical training, and training of professional welfare workers. The Reich Ministry of Labour deals with all matters affecting the care of workers and employees.

The Reich Health Office.

The Reich Health Bureau, which is under the control of the Ministry of the Interior, was founded in 1876 to assist the Chancellor and the Ministries in the drafting of legislation and in supervising the execution of laws concerning health. This Office keeps closely in touch with German scientific associations and the central health authorities of foreign countries, compiles medical and veterinary statistics, and promotes, by means of publications, knowledge of public and domestic hygiene. The works published by the Reich Health Office give the results of researches carried on by its members; the Medical Statistical Notes (Medizinalstatistische Mitteilungen) contain calculations based upon the annual statistics, while the Reich Health Office Bulletins (Veröffentlichungen aus dem Reichsgesundheitsamt) give current information as to the situation in Germany in respect of contagious diseases, the proceedings of legislative bodies, associations, &c., and the weekly and monthly statistics; an appendix is also published containing all relevant legal decisions. The Reich Health Office promotes popular education in hygiene by issuing a popular work entitled "Health Manual," as well as memoranda and pamphlets.

The Reich Health Office consists of four departments, the medical, chemical hygiene, bacteriological, and veterinary departments. Auxiliary to it is the Reich Health Council, an advisory body of which the individual members (numbering, at the present time, 75) are chosen by the Reichsrat for a period of five years from among men of prominence in the medical and veterinary spheres (men of science, practising doctors, and technical experts), the President and his deputy being chosen from among the members by the Reich Minister for the Interior. This Health Council is divided into 11 committees, viz.: (1) health matters in general (including questions relating to the health staff); (2) the control of foodstuffs; (3) the prevention of epidemics; (4) water-supply and the removal of waste products; (5) social and school hygiene; (6) factory and industrial hygiene; (7) marine and tropical hygiene; (8) population and race hygiene; (9) provision of medicaments (including the traffic in poisons); (10) veterinary matters (including questions affecting the veterinary personnel, and the inspection of slaughter-houses and meat); (11) statistics. It is the duty of the Reich Health Council to give advice, on request, to the authorities of the several States.

The laws regarding public health are executed by officials of the various Federal States, on lines laid down in the executive regulations issued by the Reich authorities.

Health Administration in the Federal States.

Where the Reich authorities have refrained from promulgating laws regarding public health, the German States, with Prussia at their head, have by their own laws organised a public health service on admirable lines. The highest Prussian health authority is the Ministry for Public Welfare. Department I. of this Ministry, which is under a doctor, deals with public health matters (including police sanitary regulations); Department II. deals with housing and land settlement, and Department III. with the care of the young and general welfare work. The Ministry also has control of the Robert Koch Institute for Infectious Diseases, the State Hydropathic Institute, two hygiene institutes, 10 medical analysis stations, two typhoid laboratories, and the State foodstuff laboratory. The Ministry is assisted by a State Health Council; for the provinces joint boards have been set up composed of lawyers and doctors. The police authorities of the provinces and districts (the Ober and Regierungspräsidenten) are advised by the Regierungs und Medizinalräte. The law of Sept. 19th, 1899, regulated the official duties of the medical officer of the "Kreis" (county), and established health committees in the communes (in places of over 5000 inhabitants). The work of the medical officers is regulated by the local police authorities (the Landrat, the Commissioner of Police, or the magistrate). It is the duty of the health committees to carry out a joint system of inspection, to support measures taken by the police authorities, to give expert advice and to make suggestions.

---

* Based on a Series of Reports on National Health Organisation to the Health Section of the League of Nations and on Statistical Handbooks prepared by the Section. Obtainable in Great Britain from Constable and Co.

In the other German States the health authorities are organised on similar lines. In many instances the technical advisory body has the title of "State Office of Health," and is, in most cases, under the control of the Ministry of the Interior (in Thuringia it is under the Ministry of Commerce). Special Health Ministries under medical administration do not exist in the Reich or in any of the States.

The work of public instruction in matters of hygiene has been energetically taken in hand by a Reich Committee and by State Committees with their subsidiary organisations. The work of welfare and health offices specially concerned with care work (on behalf of infants, tuberculous persons, persons suffering from venereal disease, cripples, &c.), which have recently been established in large numbers by the Kreis and municipal authorities, is carried on by the public medical officers, specially appointed communal doctors, practising doctors, and a carefully trained staff of care workers. The competent State authorities direct this work.

The Medical Staff.

Prussia has, at the present time, at its disposal some 449 Kreis medical officers, of whom 274 receive full-time and 175 only part-time salaries. The medical officers of the Kreise are, for the most part, recruited from Kreis assistant medical officers (rarely from practising doctors), provided that they have passed the prescribed State medical examination; "Regierungs und Medizinalräte" are recruited from Kreis medical officers; while the Ministerialräte in the medical department of the Ministry for Public Welfare are mostly chosen from among the Regierungs und Medizinalräte. The whole territory of the Reich had in round numbers 950 medical officers of the categories mentioned at its disposal. In general the service is regulated as in Prussia.

In most of the States appointment as a State health official or medical officer is conditional upon passing the examination for State doctors, the regulations for which vary but little in different States. In Prussia, which is fairly typical, the candidate must not only have followed a course of lectures on forensic medicine and taken part for at least six months in the practical work of a psychiatric clinic, but he must also have completed a full course of study in social hygiene at Breslau, Charlottenburg, or Düsseldorf. In addition, he must have taken courses of pathological anatomy, bacteriological hygiene, and forensic medicine, each of at least three months' duration; and he must have acted as assistant in a psychiatric clinic for at least three months. The candidate may not be re-examined more than once. In Prussia it is a condition of appointment as Kreis medical officer that the candidate should have worked five years as an independent medical practitioner after passing the examination.

Special regulations apply to posts as tuberculosis expert or as medical officer in charge of infants, small children, cripples or persons suffering from alcoholism, or as school doctor. It is recommended that the communal medical officers, whose duty it is to advise the communal administration in all matters of public health and social hygiene, should be required to pass the examination prescribed for Kreis medical officers. In rural Kreise the communal medical work can be carried out by the Kreis medical officer, who also takes charge of the public health and social hygiene section of Kreis welfare centres. In the larger towns appointment of special communal medical officers is necessary, subject to the control of the medical officer of the Kreis or district. Among the assistants of medical officers in combating epidemics are disinfection officials. In many Kreise special disinfection officials have also been appointed to act as "health inspectors."

The medical organisations which have been formed in all the States of the Reich are, as a rule, representative professional bodies (associations of doctors, which, in some States, are legally regulated, and often have disciplinary powers in regard to their members). Their participation in the work of public health is of importance, inasmuch as they send representatives to the various State organisations of a technical medical character, the health councils, &c. The latter utilise their services for the purpose of bringing recommendations and proposals relating to special health questions to the notice of individual doctors.

V. AUSTRIA.

The organisation of the Imperial Health Service is maintained in its essentials in the Republic. The Health Department in the Ministry for Internal Affairs has been abolished, and a special section of the Federal Ministry for Social Administration, the Public Health Office, is now the highest authority in health matters. The organisation comprises a principal board of health, provincial boards of health, district commissionerships, divisional medical officers, municipal medical officers, communal and district medical officers. The provinces (formerly Crown lands) are Vienna, Lower Austria, Upper Austria, Salzburg, Styria, Carinthia, Tyrol, Vorarlberg, and the Burgenland. Each province has its own health officers, and a provincial board of health which acts as scientific and technical adviser. Each province is divided into administrative districts (113 throughout Austria)—under a district commissioner (Bezirkshauptmann), with a divisional medical officer attached. Towns possessing a separate statute are administered politically by the mayor, instead of the district commissioner, with a municipal council. To this council is attached a municipal health officer (Stadtphysikus), while in boroughs or villages the administrative organ and scientific expert are represented by the communal medical officer (Gemeindearzt) or by a district medical officer in charge of several communes (Distriktarzt).

The law of April 20th, 1870 (Imperial Gazette, No. 68, of the "Imperial Public Health Law"), amended and supplemented, still forms the main basis of the organisation of the public health services. It places the supreme control over the whole health organisation and of all medical affairs under the direction of the Government, acting either directly or indirectly through the provincial authorities. The Government is thus responsible for the records of the health personnel and for its supervision; for the supervision of all hospitals, including lunatic asylums, vaccination establishments, and of spas; private institutions may not be established without permission from the State. The application of the laws regarding infectious diseases, the control of traffic in drugs and poison, the supervision of vaccination—these and all cognate duties are vested in the Government. The responsibility for the actual carrying out of the law, and for the promotion of activities of the public health services, rests on the communes, on lines laid down by provincial legislation which in turn are framed to give effect to the laws issued by the Government to apply to the whole Republic. Included in the duties of the communes, which are carried out by municipal or district medical officers, is the drawing up of periodical health reports and submitting them to Government authorities.

The health administration of Austria, like its political administration, is thus carried out by authorities of three grades, of which the highest is the Office of Public Health previously referred to.

The first or lowest grade are the municipal, communal, or district medical officers. Officers of the second grade are the medical officers attached to Provincial Governments. In these two grades the executive work in connexion with public health is carried out by medical men, acting under the administration of the corresponding local authority.[1]

Constitution of the Office of Public Health.

The Office of Public Health in the Federal Ministry for Social Affairs (third grade) combines executive powers with the duties of supervising and giving expert opinions and is, as has been said, the central authority on all health matters. At the present time the Office of Public Health consists of the four following departments:—

Dept. 1.—General health administration, dealing among other with matters affecting the professional standing of medical men; the education of doctors in general as well as of State medical officers; the organisation of public health under the Federal authorities. The public health aspects of social and private insurance, industrial hygiene, statistics, and health propaganda also come under the control of this department, which is further charged with the editorial work of the "Mitteilungen des Volksgesundheitsamtes" (Bulletin of the National Public Health Office).

Dept. 2 has control of measures for the maintenance of public health, including, for example, prophylaxis against and prevention of infectious diseases; bacteriological institutes for the manufacture of vaccines; the campaign against tuberculosis, venereal diseases, and alcoholism; water-supply; domestic hygiene and the hygiene of nutrition. The professional training of chemists and druggists and their status is supervised by this department as also the Institute of Chemico-Pharmaceutical Research.

Dept. 3 has the general control of hospitals administered by the State, and of schools for the training of nurses and midwives, also the care of mothers, infants, and young children, including school hygiene. Red Cross and first-aid arrangements are here dealt with.

Dept. 4, under a trained lawyer, deals with the legal aspects of public health questions, including lunacy administration.

A medical officer of the Federal Ministry of War serves as a representative of that Ministry on the Office of Public Health. In 1922 this Office had 32 doctors among its members. The procedure adopted in connexion with sanitary legislation is that the Central Office issues circular decrees to all the provincial offices, which transmit instructions to the district authorities. The Office of Public Health has no laboratories of its own for scientific research.

The Central and Provincial Boards of Health.

Over and above this administrative administration the Imperial Public Health Law provides for the establishment of a Central Board of Health, whose duty it is to assist the administration as an advisory and expert organisation. The "ordinary" members have the right to the title of Public Health Councillor and are unpaid. Extraordinary members include specialists called in as occasion requires. There are corresponding provincial boards of health whose members include the chief sanitary officials of the provinces. The chief public official of each province makes journeys of inspection throughout his district in order to supervise the application of sanitary law. The communal doctors, or municipal medical officers as the case may be, are also required to make journeys through their districts for the same purpose. On the outbreak of epidemics they must take any measures which they deem to be necessary on their own responsibility, and under inter-State agreements they are now empowered to cross the frontiers and to enforce urgent measures in association with the frontier authorities of any other country concerned. Since the National Sanitary Department forms a branch of the political administration and holds a place amongst the organisations the medical officials are subordinate in purely sanitary matters to the non-medical heads of these organisations. In the event of discord no legal guarantee is provided that the views of the medical officials will prevail. As a matter of fact, however, no disputes have arisen.

In 1918 the duties of the Army Health Service were transferred to the Office of Public Health. The present army administration has no hospital of its own and sick soldiers receive treatment in civilian hospitals.

The Training of the Health Personnel.

The professional training of all doctors, dental operatives, midwives, and pharmaceutical chemists is regulated by the State, and the requirements for courses of study and examinations are indicated in this report. Post-graduate training in order to obtain a post as doctor in the Public Sanitary Service is required, and the passing of an examination in hygiene and sanitary law, medical jurisprudence, including forensic psychology; pharmacology, including a knowledge of the commoner poisons; veterinary police regulations. The length of special training required is not specified, but it is stated that a reform of the district medical officers' examination is contemplated. As to the higher training of senior State medical officers, special courses are held from time to time in university towns. All State medical officers are Federal officials and their work under the State health administration must be conducted as their main profession. Medical officers of the first degree are not forbidden private practice.

Pharmaceutical Chemists.—A distinction is drawn between public pharmacies on the one hand and the private pharmacies of doctors and emergency pharmaceutical installations on the other. Public pharmacists are either licensed or proprietary. The applicant for authority to carry on the business of a public pharmacist must have undergone technical training for a minimum period of five years after taking his degree of Master of Pharmacy, or in the case of establishment of new pharmacists for 15 years. A doctor may only maintain a house pharmacy if there is no public pharmacy near his place of residence.

Dental Operatives.—The legal status of fully qualified dental practitioners and that of dental operatives is laid down by the State. Owing to the shortage of dental operatives just after the war special concessions were made to certain dental operatives who began a three years' course of training before Oct. 1st, 1920, but since these concessions do not apply to those who began their training after this date, the dental operative in Austria with a recognised professional status must necessarily disappear in the course of a few decades.

Midwives.—There is as yet no uniform law on midwifery applicable to the whole country. Women who wish to become midwives have to take a ten months' course of instruction in one of six Austrian instructional institutes and to pass an examination, and they are then entitled to practise midwifery as an independent profession throughout the territory of Austria. Before beginning practice they have to report to the administrative authorities and are placed under the supervision of the district medical officer. No State midwifery system has been instituted. The communes and towns have to provide midwives for prospective mothers without means. A proposal for a general midwifery law, which has been drawn up with the assistance of Prof. L. Piskacek, is awaiting consideration by Parliament.

GUY'S HOSPITAL MEDICAL SCHOOL: SENIOR SCIENCE SCHOLARSHIPS.—The following awards have been made at Guy's Hospital Medical School: O. A. Beadle, New College, Oxford, War Memorial scholarship, £80; L. T. Ride, New College, Oxford, £80.

---

[1] In Vienna the first and second grade are in the hands of the single authority, the Municipal Council.

VIENNA.

(From our own Correspondent.)

Lymphogranulomatous Tumour.

At a recent meeting of the Surgical Society of Vienna, Dr. Steindl demonstrated a tumour obtained from a woman aged 38, with a history of vague pains in the abdomen and continuous loss of flesh for a year. Clinical investigation confirmed the diagnosis of cancer of the stomach, but on operation it was found that the muscular layers of the stomach were hypertrophied, while the mucosa was replaced by a brownish, soft, cushion-like tissue, showing small yellowish nodules in its substance; the pyloric end in particular was thus affected. No ulcerations were visible, and on operation there was nothing of a pathological nature to be noted in the intestines, the liver, pancreas or the mesenteric glands. The microscopic sections of the parts removed, also of some of the glands taken from the gastro-iliac ligament and the smaller omentum, showed the typical picture of lymphogranulomatosis. Two months after operation the percentage of both mononuclear and eosinophil leucocytes had gone down considerably, while the lymphocytes had increased threefold to 36·7 per cent. Dr. Steindl claimed that this was the first case of lymphogranulomatosis localised in the stomach which had been successfully operated upon. A second case was reported by Prof. Ewald, who stated that ten years ago he had seen a woman with an inoperable and fixed malignant growth who suffered from attacks of severe dyspnœa, but showing no other symptoms of malignant disease. The surgeon attempted to diminish the size of the tumour by a partial resection, but the operation had to be abandoned and a tracheotomy was performed. Microscopic examination of portions of the tumour showed the presence not of the suspected sarcoma, but of lymphogranulomatosis. After-treatment with tuberculin and X rays caused a rapid diminution of the tumour. Since then the patient has undergone a course of X ray treatment twice or three times a year, but this is sufficient to keep the condition in check. The struma has not reappeared, and there are no enlarged glands in the neck, although a swelling sometimes appears in the mediastinum, causing attacks of dyspnœa.

Flora and Fauna of Hot Springs.

Prof. Hans Molisch, who for the past three years has been working in the botanical and physiological institute of the University of Tokio (Japan), read a very interesting paper in the Biological Society of Vienna on his return to this city. In certain districts of Japan, he said, nearly every house has its own hot spring. He investigated the flora and the fauna of these springs and found that, up to the temperature of 69° C., living organisms, such as bacteria, algæ, amœbæ, infusoria, rotifers, and eels, could exist therein. The most interesting organism, however, is the cyanophyceæ. This group of algæ flourishes in water at a temperature which kills off, in a short time, all other living organisms. They can also live in ordinary water, and the spores of these plants are present in nearly all springs and rivulets in large numbers. Prof. Molisch thinks that the thermophile bacteria and algæ are the direct descendants of the aboriginal organisms which inhabited the earth at a time when its surface and its waters were very hot.

Outbreak of Typhoid near Vienna.

Typhoid fever in our city is such a rarity, thanks to our mountain water-supply, that many students of medicine here never see a case in the hospitals. There was some excitement, therefore, when it became known that in a small holiday resort near Vienna a few cases had occurred; 25 persons were infected and four died before radical measures for the control of the outbreak were instituted by the local authorities, a rather regrettable delay. It appears that the epidemic has been introduced by visitors returning from Italy. This year many holiday makers and "sun-seekers" travelled from Austria to Italy, especially to the eastern coast, and it is presumed that the unwonted kind of food, as well as the large quantity of fruit consumed there, upset the digestions of many of these excursionists, and in addition was responsible for the original cases of typhoid. In connexion with this occurrence very marked attention is being paid now to a new possible source of contamination of the Vienna water-supply; 40 per cent. of the water is supplied by wells and springs originating in the Rax mountains, which lie about 60 miles south-west from Vienna, and are some 6500 feet high. The wonderful scenery of this Alpine district attracts enormous numbers of visitors yearly, and a funicular railway to the summit of the Rax plateau is now under construction. The Board of Health of Vienna, however, has recently pointed out that the influx of visitors following on the construction of the railway will constitute a potential source of contamination of these springs, and thus threaten the health of Vienna. The Board advises either the cessation of the railway work until all springs are adequately protected, or else the construction of a new water-supply. It must be added, however, that geological experts nevertheless regard such fears as groundless, since the geological strata intervening between the course of the railway and the springs are more than sufficient to guarantee perfect sterility of all water that might possibly trickle through to the springs.

MEMORIAL TO HIPPOCRATES.

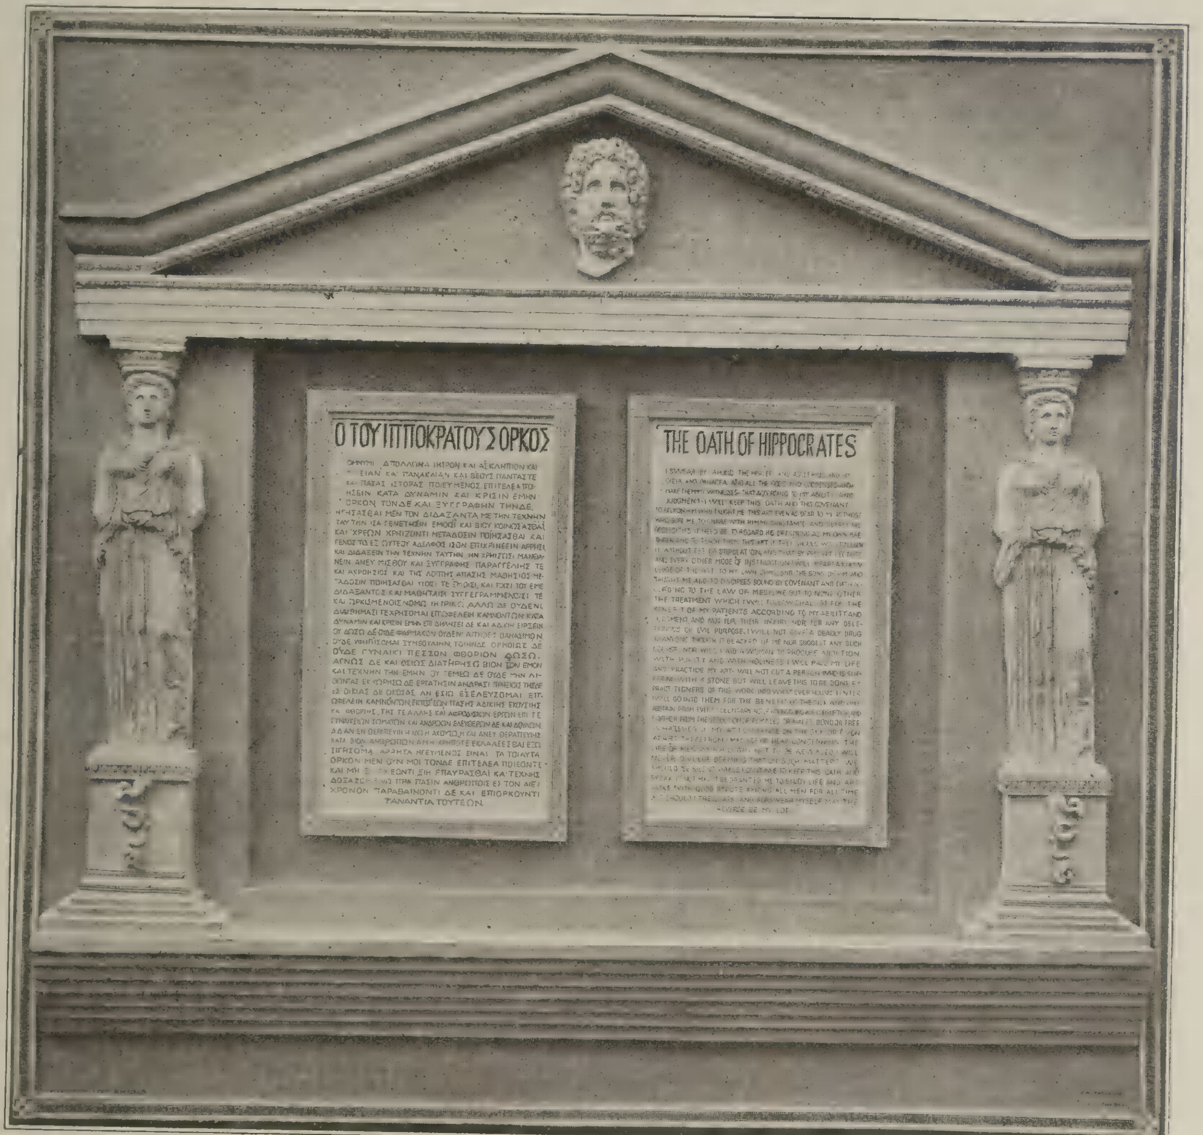
Dr. Ernest Mayer Neville, of Ealing, London, W., has conceived, designed, and executed personally a memorial to "Hippocrates, the Father of Medicine." The memorial is a presentation of the "Oath of Hippocrates" in a setting of classic Greek antiquity. It will be seen from the reproduction given below that this conception is expressed through the medium of a Greek temple, at the entrance of which are placed two tablets, bearing the oath engraved in Greek and English.

The Hippocratic oath is given in the original classic Greek form (Ionic dialect, edition Littré) side by side with the English translation. The spatial distribution of the texts has been arranged in a symmetrical, compact, and organic manner, in correspondence with the general architectonic design of the memorial. They are engraved in classic Greek fashion on oblong tablets which have ornamental borders and corners of classic Greek design. In the English translation the author has striven to keep as close to the original text as is compatible with English phraseology and meaning. The initial part of the oath has been emphasised by treating it separately as a kind of preamble, and the end of the oath has also been accentuated by letting it stand out quasi as a finale, a warning memento. (T'Anantia Toyteon—Reverse be my Lot.)

The tablets are flanked by caryatids, draped figures from the temple of Erechtheus (Erechtheion) on the Acropolis of Athens, a building in pure Ionic style (original specimen now in the British Museum, of which they are direct copies). They are raised on pedestals, which are replicas in style of the original wall on which the caryatids of the Erechtheion stood. The face of each pedestal is guarded by a snake, the symbol of medical art and perspicacity, copied directly from the original statue of Apollo Citharoedus (Cyrene) in the British Museum. These snakes are conspicuous through their natural and graceful poise and the other reptilian characteristics. The caryatids support the entablature and the pediment, Ionic in order. The centre of the pediment is held by the dominating head of Asclepius, the God of Medicine, expressive of exquisite physical beauty, serene wisdom, and divine benevolence; it is a direct copy of the original in the British Museum. The snakes mentioned above have their gaze fixed upon this head, as if compelled by its magnetism. The whole structure of the temple rests, in accordance with classic Greek feeling, on steps, of which there are seven, a number symbolical of spiritual values. The background of the memorial is bordered by classical ornamental design.

The original is in plaster-of-Paris, 5 ft. by 5½ ft., weighing 250 lb., and has been on private exhibition to leading British medical men. It was also inspected on the occasion of the visit of the Inter-State Post-Graduate Assembly of America. As a result of suggestions made, a large-size photogravure de luxe of the tablet will be reproduced by a well-known house and published in limited numbers for the medical profession only.

THE MEMORIAL TO HIPPOCRATES.



Translation of the Oath.—I swear by Apollo the healer, and Asclepius, and Hygieia, and Panacea, and all the gods and goddesses—and I make them my witnesses—that, according to my ability and judgment, I will keep this oath and this covenant: to reckon him who taught me this art even as dear to me as those who bore me, to share with him my substance and supply his necessities, if need be, to regard his offspring as my own brethren, and to teach them this art, if they should wish to learn it, without fee or stipulation, and that by precept, lecture, and every other mode of instruction, I will impart a knowledge of the art to my own sons, and the sons of him who taught me, and to disciples bound by covenant and oath according to the law of medicine, but to none other. The treatment which I will follow shall be for the benefit of my patients, according to my ability and judgment, and not for their injury, nor for any deleterious or evil purpose. I will not give a deadly drug to anyone, though it be asked of me, nor suggest any such course, nor will I aid a woman to procure abortion. With purity and with holiness I will pass my life and practise my art. I will not cut a person who is suffering with a stone, but will leave this to be done by practitioners of this work. Into whatever houses I enter I will go into them for the benefit of the sick, and will abstain from every voluntary act of wrongdoing and corruption, and further from the seduction of females or males, bond or free. Whatever in my attendance on the sick or even apart therefrom, I may see or hear concerning the life of men which ought not to be revealed, I will never divulge, deeming that on such matters we should be silent. While I continue to keep this oath and break it not, may it be granted me to enjoy life and art alike, with good repute among all men for all time. But should I trespass and forswear myself, may the reverse be my lot.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 619.)

Joint Tuberculosis Council.

(App. XCIII. and Q. 22184–22251.)

THIS Council claims to represent the collective views of medical men engaged, officially or otherwise, in combating tuberculosis. Sir Henry Gauvain and Dr. Lissant Cox presented the evidence.

It was submitted that the special measures adopted in fighting tuberculosis, in association with the general advance in other public health work, have done their part in reducing the mortality from this disease, and that, apart from the actual fall in the death-rate from this disease, the number of "carrier" cases was diminishing, and also that—

> The education of tuberculous patients in elementary hygienic methods and the isolation in hospitals of infective cases from overcrowded and insanitary homes is having, and is bound to have, a beneficial effect on the number of new cases occurring.

All tuberculosis work now centres in the dispensary, which is not ordinarily a centre for treatment but for diagnosis, with the aid of the special facilities which exist at the dispensary, and for consultation between the tuberculosis officer and the general practitioner. The Council urged that there should be a special extension of sickness benefit for tuberculous persons, as their premature return to work is positively harmful to themselves and to their families. The opinion was expressed that societies should use their surpluses to aid specially research and care work in connexion with tuberculosis.

The return of patients from the sanatorium to their original occupations was advisable, the insured person being given part-time employment and continuing to receive sickness benefit, subject to more or less continuous medical supervision.

> Would you expect any trade-union objections to such part-time arrangements ?—No, not so long as the arrangements were not abused.
>
> Would you anticipate that employers would willingly meet the difficulties of organisation of their work consequent upon taking on part-time men who probably would require special arrangements in view of their medical history ?—We do not suggest that employers should be expected to alter their arrangements for odd cases, but most cases, we think, could be fitted in without special arrangements upsetting other workers.

The witnesses said that the part-time employment of men in their ordinary occupations should have a sympathetic public opinion behind it, and that it was preferable to establishing colonies—indeed, they doubted if the Papworth experiment, while in itself a brilliant success, could be reproduced generally under public management.

Cambridgeshire Tuberculosis After-Care Association.

(App. LXXXIII. and Q. 20856–20931.)

Dr. P. C. Varrier-Jones and Mr. Bunnett gave evidence. They pointed out that the Insurance Act presupposes that insured persons will either be wholly incapable of work or else will be able to earn a normal wage, and that, in the special case of the tuberculous person, to limit cash payments to those who are wholly incapable of work is definitely harmful to the treatment of this disease, and brings with it serious and expensive consequences.

> One of two things happens at the present time : either the patient is afraid to work at all (a six months' stay in a sanatorium makes it the more difficult to begin again), because he fears that he will be unable to stand the strain ; or the patient attempts a full day's work under commercial conditions and almost immediately breaks down.

The longer the ex-sanatorium patient is kept as a productive unit of society, the less fear is there of the family's resistance being lowered and of the spread of the disease among them. This point has been proved at the Papworth Village Settlement, where up to the present, with graduated sheltered employment for the bread-winner, no case of pulmonary or other tuberculosis has been discovered in the children.

The payment of sickness benefit to a partially incapacitated tuberculous person could be justified on the ground that the gradual employment of the tuberculous person prevents the spread of infection. Certificates should be given signed by the general practitioner and countersigned by the tuberculosis officer. Such partial employment can best be carried out under sheltered conditions in a colony such as Papworth.

> We do not attempt to train a man to be a carpenter, or whatever it may be, and return him to the outside world, because the competition is too great ; but we are able to set him up in workshops in the Village Settlement and provide him and his family with proper housing conditions, and they remain there for the rest of their lives, earning wages in the industries which now have a turnover of over £50,000 a year.

About 75 to 80 per cent. of the men in the Village Settlement are ex-Service men in receipt of a pension, and Dr. Varrier-Jones is anxious, by the operation of a scheme of sickness benefit for partly employed tuberculous men, to place the ordinary civilian in the same economic position as the ex-Service men.

The London County Council on the Treatment of Tuberculosis.

(App. LXXXIV. and Q. 20932–21050.)

This evidence, given by Mr. G. H. Walmisley, did not differ in any material respect from the evidence given by the Joint Tuberculosis Council and the Cambridgeshire After-Care Association.

Grants from the National Health Insurance Funds were recommended to be made in aid of approved work-centres at which post-sanatorium cases could be employed under the medical supervision of the tuberculosis officer, and it was also proposed that the surpluses of Approved Societies should be applied in part for the assistance of tuberculous persons on a similar basis to the provision made for ex-Service men by the British Red Cross and United Services Fund.

The experience of the Council, generally, and the operation of an experimental scheme at Hatton Garden in particular, and also the discouraging result of efforts to find suitable employment for tuberculous persons in the open market, have led the Council to the view that work-centres offer the most favourable opportunity for the employment of many such persons. As to persons suffering from other complaints the witness said that he knew of none to which the same arguments would apply with equal force.

> Have you ever considered whether there is a practicable case for doing something for the blind man to get half a day's remunerative work on the lines of your tuberculosis scheme ?—I think the cases are similar to a certain point, but you do not, in the case of the blind, get the result, by doing this part-time work, of improving the man's health.

Financial aid was essential to place the ordinary civilian in the same economic position as the ex-Service man with his pension.

British Social Hygiene Council.

(App. LXXXII. and Q. 20760–20855.)

The National Council for Combating Venereal Diseases, founded as a voluntary organisation in 1914, has, since 1918, been in receipt of an annual grant from the Ministry of Health for certain approved forms of propaganda work. It became an incorporated body in 1922. It is now known as the British Social Hygiene Council.

Evidence was given by Mr. E. B. Turner, Dr. Otto May, Mr. Leonard Bowden, and Dr. P. A. Clements.

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus : "App. X. 69," and references to the oral evidence thus—Q. 1369.

It was pointed out that there is no permissive clause in the National Health Insurance Act by which Approved Societies or Insurance Committees, if they so desire, may contribute from their benefit fund to the funds of the National Council or, indeed, any society engaged in research or health propaganda. It was also urged that the medical benefit regulations should be amended to provide for more detailed certification, and also that efforts should be made to improve the equipment of the general practitioner so as to enable him to make adequate modern diagnosis and give the required treatment.

> Of the whole of the practitioners in London there are only 400 men who are qualified to be supplied with free salvarsan, and those 400 are the result of a very intensive campaign which was carried on in 1917 to 1918. . . . The ideal we should like would be that the practitioners throughout the whole country should be the first line of defence against these illnesses, that they should be encouraged in every way to become absolutely *au fait* with modern up-to-date methods, and that they should then employ them the moment they come across their cases.

The London Insurance Committee.

(App. XCVIII. and Q. 22838–22974.)

Mr. Henry Lesser gave evidence as to the working of the medical benefit scheme in London. He urged that the whole of the skill of every insurance practitioner should be available for his patients without charge, and he agreed that it was essential that this recommendation should go hand in hand with the Committee's wider proposal that a complete general practitioner service with a coördinated hospital service should be made available to insured persons at the earliest opportunity.

The Insurance Committee should have power, it was suggested, to refuse admission to the panel when, after consultation with the Panel Committee, they thought this to be desirable. The largest panels should be further limited with the advantage, amongst others, of enabling young practitioners to get a footing in the service. The witness said that the Committee were not in possession of evidence to show that the London medical service was inferior to that given elsewhere. He said that it was a fair and an improving service.

Amongst minor recommendations the Committee said that power should be given to the Medical Service Subcommittee to require witnesses to give evidence on oath, and that in the case of an appeal made by a practitioner against a decision of the Committee costs should be awarded to follow the result of the appeal.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. A. F. Fleming is placed on the Retd. List with the rank of Surg. Capt.

Surg. Lt. A. G. Bee to be Surg. Lt.-Comdr.

R. C. Foster to be Surg. Lt.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lt. (D.) C. H. A. Fido to be Surg. Lt. (D.).

ROYAL ARMY MEDICAL CORPS.

Maj. W. C. Nimmo, from half-pay list, retires on ret. pay on account of ill-health.

Maj. R. C. Wilmot to be Lt.-Col., vice Lt.-Col. F. W. W. Dawson, ret.

Capt. G. L. K. Finlay to be Temp. Capt., and relinquishes the rank of Capt.

ARMY RESERVE OF OFFICERS.

2nd Lt. J. V. Dockray, from the Buffs, Reg. Army Res. of Off., to be Lt.

TERRITORIAL ARMY.

Capt. J. Walker to be Maj.

ROYAL AIR FORCE.

Flying Officer S. G. Gilmore and R. H. Stanbridge are granted permanent commissions in the rank stated.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics of a city, six county boroughs, and one Scotch burgh for 1924 :—

Name of town.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Coventry C. ..	132,000	16·0	9·6	1·11	1·12	1·8	37	79	4·2
Stockport C.B. .	126,000	16·4	13·9	1·16	1·33	3·8	29	87	5·8
Preston C.B. ..	123,100	18·9	13·9	1·13	1·29	3·6	42	97	6·0
Huddersfield C.B.	111,800	14·5	14·0	1·08	1·57	3·8	48	97	3·7
Halifax C.B. ..	98,750	14·9	15·3	0·71	—	—	57	96	4·0
Northampton C.B.	93,590	16·4	11·1	1·10	1·39	2·2	25	52	4·6
Paisley B... ..	86,647	21·6	16·1	1·06	1·25	3·7	47	139	9·6
Warrington C.B.	78,120	21·0	11·6	1·41	1·07	2·6	30	84	4·3

C. = city. C.B. = county borough. B. = burgh.
— = not given.

Coventry.

Dr. E. H. Snell reports that the usual re-inspection was made of all the houses which have been converted from "back-to-back" to "through-ventilated" houses since 1909 ; and these houses were, without exception, found to be properly occupied as through-ventilated houses. In discussing the cause for the rise in the infant mortality-rate in 1924, as compared with the previous year, Dr. Snell points out that in addition to the increase of 2·5 for whooping-cough and 2·9 for bronchitis, there is a rise of 4 per 1000 births for diarrhœa. The summer of 1924 was cold and wet and an increase in the diarrhœa-rate was not to be expected. Dr. Snell says it is impossible to avoid the conclusion that some of this increase in the infant mortality-rate is due to the set-back in the work of the health visitors, caused by the reduction of their number from ten to five at the beginning of 1923. The number has now been increased to eight by the last addition to the staff in October, 1924. Only 18 specimens of milk were examined for tubercle, the results being negative; and Dr. Snell points out that the absence of legislation forbidding the movement of cows found to be giving tuberculous milk almost nullifies the advantages of the milk clauses, although this will, it is hoped, be remedied by the re-introduction of the Tuberculosis Order.

Dr. J. McG. Williams reports as the most notable event of the year the opening of the King Edward VII. Memorial Sanatorium, which occupies a fine position on the high ground of Hartford Hill, about two miles from Warwick. The sanatorium accommodates 66 men, 50 women, and 34 children, and is intended for early cases only. The institutional treatment of tuberculosis is carried out by the Warwickshire and Coventry Joint Committee for Tuberculosis which also used the Bramcote Sanatorium as their second institution. Dr. Snell thinks that one of the greatest objections to such delegation of the institutional treatment of tuberculosis to a special committee with its own medical officers, is the fact that there is thus formed a more or less water-tight compartment with a tendency to regard the treatment of the patient as the beginning and end of the campaign against tuberculosis. The Ministry of Health have always advised that tuberculosis officers should be closely associated with the preventive measures of the local authority. With a view to bringing about such an association, the Joint Committee have forwarded to the various sanitary authorities of the county the recommendation of the Ministry that the tuberculosis officers should be also appointed assistant medical officers of health. Some of the sanitary authorities fell in with the proposal, but others, amongst which was the city of Coventry, did not.

Stockport.

Dr. Arthur G. Jenner records 37 notifications of encephalitis lethargica with eight deaths. In two cases there was evidence of direct infection. The borough maternity home, "Glebe House," with its eight beds, admitted 192 cases during the year. The average stay of each patient was 14 days, and no maternal deaths occurred. As the accommodation at Glebe House is inadequate, the corporation have purchased the Mile End Hall Estate where, after the necessary alterations have been carried out, there will be accommodation for 15 cases. The number of new houses erected during 1924 was 241, as compared with 176 during the previous year, and the number in course of building at the end of the year was 351. In spite of this improvement, Dr. Jenner calls attention to the lack of houses of the smaller type. Only 11 samples of milk were examined for tubercle, a positive result being obtained in one instance. Six cases of typhoid fever were notified, two of which were traced to the eating of mussels, but the names of the vendors of the mussels could not be ascertained.

Preston.

Dr. F. A. Sharpe says the pollution of the atmosphere by industrial smoke demands more attention from his committee than it has hitherto received and recommends the appointment of an inspector, trained in boiler management, with the suppression of smoke as his one duty. The beauty of the town revealed in the clear smokeless weather prevailing last Whitsuntide was, he says, a matter of universal comment and delight. The Preston Committee still adopt the over-generous limit of five minutes black smoke in a half hour observation.

Dr. Sharpe gives an interesting account of an unrecognised outbreak of small-pox at a boys' home. On Feb. 16th he was asked to see a girl resident at a laundry and gave his opinion that the patient was suffering from chicken-pox, but he arranged for her removal to the isolation hospital. In a day or two the symptoms became suggestive, and after consultation, Dr. Sharpe decided that the case was one of small-pox. Inquiries showed that the laundry did work for a boys' home, and it was found that at the boys' home there had been 15 cases, the first beginning on Christmas Day and the last on Jan. 12th, of an ailment considered to be chicken-pox. The outbreak at the boys' home infected all but one of eight boys who were not protected by vaccination; it also infected 7 out of 56 boys who were protected by vaccination, and it immunised the boys who were attacked against successful revaccination. All the cases were of a mild type.

Captain R. Finch, the veterinary surgeon, shows that energetic efforts are being made to improve the milk- and meat-supply of Preston. Out of 162 samples of mixed milk examined for tubercle, 19 gave a positive result. In each case the positive sample was followed in order to eliminate the cow or cows giving tuberculous milk. In 16 cases the cows with tuberculous udders were found. At two of the farms there were two cows with tuberculous udders. In the three remaining cases where the tuberculous udders could not be found, animals had been sold off the premises prior to the visit of the veterinary surgeon. There are no Grade A producers in Preston and there is one retailer licensed to sell Certified Milk.

Huddersfield.

Dr. S. G. Moore reports that 323 new houses were erected during 1924. Of these 69 were built by the corporation and 254 by private enterprise. Of these latter 156 were built with State assistance and 174 were suitable for members of the artisan class. Nevertheless Dr. Moore tells us that no one in possession of adequate information can question that at the present time there is grievous lack of dwellings for the people of the borough. Under the scheme for the voluntary notification of pregnancy 568 notifications were received, the total births being 1627. Four "home helps" are employed to take over the household duties in the homes of maternity cases, and two charwomen for the washing and heavy cleaning. Seventy-two samples of milk were examined for tubercle and five were found to be infected.

Halifax.

Dr. Cyril Banks reports that the deaths in Halifax (1511) exceeded the births (1481). Ten cases of typhoid fever were notified with one death. When blood tests were carried out the type of disease was found to be paratyphoid B. Five of the cases occurred at an unusual time of the year—namely, in the first half of May. Similar outbreaks occurred in other parts of the West Riding and the medical officers of health pooled their experiences, but no origin could be assigned and no particular article of diet was incriminated. There were 38 notifications of diphtheria with five deaths. Of the four deaths which occurred in the fever hospital, three of the patients were admitted in a moribund condition, illustrating the need for immediate medical advice for sore throat and the early administration of antitoxin. Dr. Banks is doubtful as to the value of hospital treatment for broncho-pneumonia complicating measles. The outlook when pneumonia has set in is not good. Wards set aside for such cases would remain idle for long periods and the difficulty of securing nurses at short notice is considerable. Influenza reached its height about the middle of March. In this epidemic the illness began suddenly with shivering and pains in the head or back. There was great prostration and in many cases vomiting with or without abdominal pain. Diarrhœa was frequently present. The temperature was high for three or four days and recovery was slow, there being loss of appetite, irritability, loss of temper, and great mental depression. There were 73 deaths recorded, being more than the deaths from all forms of tuberculosis. The suggestion is put forward that certified midwives should wear a badge, in order to distinguish them from untrained women.

Northampton.

Dr. J. Doig McCrindle reports that scarlet fever of a mild type was very prevalent; 1056 cases were notified with six deaths. A table shows that this is the largest number of notifications since 1904, when there were 2224 cases with 40 deaths. The provision of new dwellings does not keep pace with the needs of the people and the unsatisfactory housing conditions continue with little alleviation. The methods of scavenging and refuse disposal are commented on adversely. Only a small portion of the refuse is dealt with at the destructor, which is situated in a populous district and is a frequent cause of complaint. Most of the refuse is deposited on tips, which are a source of nuisance to the surrounding inhabitants. The maternity and children welfare committee obtain the milk which they need from a company with a Grade A licence. The clinical tuberculosis officer, Dr. Stephen Rowland, does not accept the conclusion of the Medical Research Council that phthisis is especially prevalent in the boot and shoe industry, and instances the fact that the phthisis death-rate for Northampton is the same as that of the whole country. In a recent issue it was pointed out, however, that Sheffield has the lowest death-rate from phthisis of the 17 towns with a population exceeding 200,000, in spite of the proneness of the grinder to develop phthisis. One is led to the conclusion that apart from these two trades conditions of life in both Sheffield and Northampton are less liable to produce phthisis than the average conditions of other towns.

Paisley.

Dr. G. V. T. McMichael says the exceptionally high death-rate was due to the excessive prevalence of diseases affecting the respiratory system, such as pneumonia, bronchitis, influenza, measles, and whooping-cough. Arrangements have now been made for Paisley to use the West Renfrewshire Small-pox Hospital, thus enabling the Gockston Hospital to be reserved solely for tuberculosis. Dr. McMichael favours the home treatment of mild cases of scarlet fever, thus leaving hospital accommodation for more serious diseases, such as acute pneumonia, measles, and whooping-cough. Of the 23 maternal deaths associated with childbirth, four were assigned primarily to tuberculosis and three to influenza. The incidence of rickets in Paisley is steadily rising and the rise was specially marked during 1923 and 1924. Dr. McMichael attributes the rise to the distressing economic conditions and the lack of a sufficiency of milk for infants and young children. When the Russell Institute is opened, facilities for the treatment of rickets by artificial sunlight will be available. The Scottish Board of Health has expressed its appreciation of the work of the Barshaw Maternity and Child Welfare Hospital. Dr. McMichael suggests that some public-spirited citizen should come forward and erect a convalescent home for young children. The very large proportion of houses of one or two rooms in Paisley makes the work of the tuberculosis dispensary very difficult. Thus, of 170 notifications of tuberculosis investigated during the year, 111 patients shared a bed, 37 had a bed to themselves but shared a room, and 22 cases had a room to themselves. The housing difficulties are still further brought out by the birth records. Thus there were 420 births in one-roomed houses and 783 in two-roomed houses. Further, there were eight births in one-roomed houses where the parents were lodgers, and 170 births in two-roomed houses where the parents were lodgers. The total number of births during 1924 was 1893.

Warrington.

Dr. G. W. N. Joseph reports that the scheme for obtaining a water-supply from North Wales did not materialise and that a joint committee representing many water authorities in South-West Lancashire, with a representative of the Ministry as chairman, is considering the water requirements of this area, and how such requirements can best be met. There were 13 notifications of encephalitis lethargica with seven deaths. During 1924 66 new houses were built by private enterprise, none by the local authority. One hundred and eight municipal houses, however, are in course of erection and expected to be tenanted during 1925. Many applicants on the waiting-list for houses are purchasing houses erected by private enterprise and taking advantage of the Small Dwellings Acquisition Act. Of the 1662 applicants on the waiting-list there are 735 living in overcrowded houses. The committee have not been able to deal at all with 216 applicants who live outside the borough but are working in Warrington. Ninety-two tenants of corporation houses have received permission to take lodgers, but it is pointed out that all the houses concerned have three bedrooms and that there is no overcrowding. There were 88 samples of milk examined bacteriologically and seven were found to contain tubercle bacilli; five of the cows which were giving tuberculous milk were found and dealt with.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 19TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 28; scarlet fever, 1888; diphtheria, 953; enteric fever, 91; pneumonia, 578; puerperal fever, 29; cerebro-spinal fever, 3; acute poliomyelitis, 13; acute polio-encephalitis, 1; encephalitis lethargica, 40; dysentery, 12; ophthalmia neonatorum, 94. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 12 from measles, 9 from scarlet fever, 40 from whooping-cough, 26 from influenza, and 35 from diphtheria. There were 220 deaths of children under 2 years from diarrhœa and enteritis, as compared with 219, 230, 218, and 177 in the preceding weeks. In London itself the deaths from diarrhœa and enteritis in children under 2 years numbered 55, as compared with 43, 38, 40, and 28 in the preceding weeks; there were 7 deaths from diphtheria, 5 from whooping-cough, and 7 from influenza.

Obituary.

JAMES WILLIAM RUSSELL, M.D. CAMB., F.R.C.P. LOND.

James William Russell, whose death occurred on Sept. 20th at Hay Tor, Devonshire, was senior physician to the General Hospital, Birmingham, and joint professor of medicine at the University. Born in 1863 into a well-known Birmingham family closely connected with the medical profession, and educated at the Edgbaston Proprietary School, he went up to Cambridge where he graduated with honours in mathematics and took his M.A. degree in 1890. His medical studies were continued at Queen's College, Birmingham, and Guy's Hospital. Qualifying in 1890 with the M.B., B.Ch. Camb., he obtained the M.D. in 1893 and in the same year became a Member of the Royal College of Physicians of which he was elected a Fellow in 1905. After filling the posts of resident obstetrician and house physician at Guy's Hospital he returned to Birmingham as resident medical officer to the General Hospital in 1891, and 15 months later became assistant physician. He had an unusually long wait before becoming full physician in 1912. For several years he was assistant to the chair of medicine at the University, and subsequently became joint professor of medicine, a post which he held to the time of his death.

The number of consulting posts he held at hospitals in the Midlands testifies to the wide regard paid to his eminence as a physician. He was consulting physician to the Birmingham and Midland Ear and Throat Hospital, the Royal Institution for the Blind, the Midland Counties Asylum, the Sutton Coldfield Cottage Hospital, the Nuneaton Hospital, the Guest Hospital, Dudley, the Smallwood Hospital, Redditch, and the Corbett Hospital, Stourbridge. He served a term on the Council of the Royal College of Physicians and was one of the examiners for the Conjoint Board. Locally, he had a special interest in the Birmingham Medical Benevolent Society.

Although he was not a voluminous writer, he at one time edited the *Birmingham Medical Review*, and was on the editorial board of the *Quarterly Journal of Medicine*. From the fullness of his knowledge he could have contributed much to medical literature, but his characteristic modesty and self-criticism prevented publication until the material had been worked up in great detail and he had subjected it to every possible criticism. It is not sufficiently recognised that he was the first in this country to describe a case of polycythæmia rubra. In a paper published in THE LANCET, Feb. 22nd, 1902, under the title of "An Unexplained Condition of Chronic Cyanosis," he gave the details of a case which he had watched for ten years and of three similar cases recorded by others. He pointed out that the condition was a distinct clinical entity. Osler's well-known paper did not appear until a year later. He was especially interested in nervous diseases and published papers on chorea and epilepsy. In a paper in The Lancet, 1904, he gave the after-history of many cases of gastric ulcer with the object of deciding the criteria for surgical interference. More recently he had been interested in the problems of renal disease, and published in the *Quarterly Journal of Medicine*, January, 1923, a noteworthy study of orthostatic albuminuria by means of graphic records, based upon his Ingleby Lectures delivered in the University of Birmingham the previous year. He reached the conclusion that there was a group of mild kidney lesions which revealed themselves chiefly by the inability of the kidney to bear, without leakage of albumin, the circulatory disturbance brought about by the upright position, and that the orthostatic albuminurias belong to this group though at its mildest extremity. Some further studies on this subject are embodied in a paper which appears elsewhere in this issue of The Lancet.

Apart from his professional interests, he had two great sources of pleasure and recreation—music and mountains. He was a violinist above the average and was one of the chief promoters of the promenade concerts at the Theatre Royal, Birmingham. Even greater was his love of mountains. Initiated by his uncle, Sir Alfred Wills, whose first ascent of the Wetterhorn in 1854 was the beginning of the sporting side of mountaineering, he became in his younger days an expert rock climber. He never made any ice climbs, but except during the war there were few years that he did not visit the Alps. His career was unfortunately interfered with at times by spells of ill-health. During his undergraduate days he was a martyr to asthma, and although this became less after his return to his native town, the demands of a large consulting practice, and especially the added strain during the war of his work at the 1st Southern General Hospital, to which he was attached as major, R.A.M.C.T., were too much for his spare frame; signs of pulmonary tuberculosis showed themselves and necessitated a prolonged rest. Although he recovered he was obliged to restrict his practice and take precautions to avoid the attacks of bronchitis and asthma to which he became subject in recent years.

By the University and General Hospital his loss will be greatly felt, as in an unobtrusive way his devoted service, high ideals, and intellectual capacity did more than he ever realised to guide policies and influence conduct. Among a number of letters we have received one signed "General Practitioner" speaks of unselfishness carried to a fine art and uncompromising devotion to principle. His colleagues and a wide circle of doctors and patients mourn the loss of a courageous and inspiring friend. Dr. Russell was unmarried, and to his two surviving sisters we offer sincere sympathy.

LIVERPOOL PSYCHOLOGICAL SOCIETY.—The third session of this Society will begin on Oct. 6th, when Mr. G. C. Field, the President, will deliver his inaugural address at the University. The proceedings of the Society are of a strictly scientific character, and due prominence is given to the medical and psycho-analytical aspects of the subject; an unusually interesting syllabus has been arranged for the winter. Particulars may be obtained from the Secretary, the University, Liverpool.

DONATIONS AND BEQUESTS.—The governors of the Royal Manchester Children's Hospital have received £1893 from the Manchester and Salford Medical Charities Hospital Sunday Fund, and a legacy of £1000 to endow "the Eliza Entwistle cot."—Mr. John Stephen, of Hessle, Yorks, bequeathed £2000 to the University of Aberdeen, "in memory of a happy boyhood spent in that city," for scholarships, and £2000 "in memory of a happy life spent in my adopted city of Kingston-upon-Hull, for the endowment of university scholarships to boys from Hymers College, Hull."—Towards the £500,000 required for rebuilding part of the Middlesex Hospital, £201,600 has been raised. Recent gifts include £500 from the Hon. John Nivison, £250 from the Middlesex Hospital Club, £105 from Messrs. D. H. Evans and Co., Ltd., £100 from Lady Salomons, and £100 from Messrs. Chappell and Co., Ltd.

"Audi alteram partem."

THE REGULATION OF NURSING HOMES.

To the Editor of The Lancet.

Sir,—In view of the introduction last February by Mr. Gerald Hurst, K.C., of the Nursing Homes Registration Bill (England) promoted by the College of Nursing, it may be useful to record experience in Johannesburg in which, with its large boarding-house and flats population, the demand for nursing homes is very considerable. It is, of course, essential that such places be properly constructed, equipped, and administered. The writer is unaware, however, of any English standard of arrangements, though a paper containing certain suggestions and plans for high-class private hospitals and clinics was published in The Lancet[1] in 1922 by Sir Holburt Waring, of St. Bartholomew's Hospital. He stated, as regards London, that "for the most part our so-called private hospitals and nursing homes are merely adapted second-class private dwellings," and concluded with the interesting observation:—

> "It has always seemed strange to me in connexion with English people that they are quite prepared, when they have money and wish to take a holiday, to hire two or three rooms in a hotel of the best kind they can afford. But, if it so happens that they are ill and require serious medical or surgical attention, they are often quite prepared to go into what is little better than a third- or fourth-class lodging-house in a back street where the necessary surgical or medical advice and treatment are carried out."

In 1911 Johannesburg took powers to make by-laws as to municipal licensing, water-supply, sanitary requirements, separate accommodation for staff, and mortuary provision. These by-laws, believed to be the first of their kind, were sanctioned in 1914, and their enforcement quickly secured much-needed betterment. In 1922 the Union Government published regulations under the Public Health Act, 1919, S. 135 (2), dealing especially with Government registration, medical inspection, and the keeping of a detailed register of patients. Thereafter, at the request of the Government, the writer undertook a systematic inspection of nursing homes, some 37 in number, under systematised headings. No responsibility was, however, accepted as to the conduct of these places.

In the course of inquiry as to sanitary conveniences, prompted by disastrous personal experience many years ago at the hands of a certificated nurse, special attention was directed to the cleansing of bed-pans. In only five of the homes was satisfactory slop-sink and sluice provision made. In several cases it was admitted by highly trained English and South African nurses that the bath was used for cleansing and rinsing purposes. This is obviously and specially likely to occur where the water-closet is situated alongside the bath. In other respects the results of inspection were rather surprisingly satisfactory. The replacement of numerous adapted "second-class private dwellings" (usually small bungalows) by buildings of modern design and equipment may in some cases be preferable; but this, like technical equipment, quality of cooking, standard of nursing, attendance, and tariffs, is largely a question of demand, supply, and competition, which can hardly be dealt with by regulation. Nursing homes should certainly be in a state of good structural repair, possess a sufficiency of private open space or garden, be provided with water carriage wherever practicable, and, without any exception, possess adequate and approved slop-sink and sluice provision on each nursing floor. Sufficient and, in the larger homes, separate bathing and sanitary conveniences should be available for patients and staff; in no nursing home should a sanitary convenience be permitted in a bathroom. Licensees should be supplied with, and produce on demand, an authorised schedule of the number of beds permitted in each room, and should not be overburdened with record-keeping, if only to induce them to keep their essential register with reasonable diligence and accuracy. In regard to *standard of nursing*, 54 per cent. of the staff were certificated generally and in midwifery, 15 per cent. in midwifery only, 9 per cent. were probationers, and 23 per cent. were untrained.

---

[1] The Lancet, 1922, ii., 697.

As a result of this inspection, the existing 1915 municipal by-laws were revoked to be replaced by the regulations which I here append.

I am, Sir, yours faithfully,
CHARLES PORTER, M.D. Irel., D.P.H. Camb.,
Medical Officer of Health, Johannesburg.
August 1st, 1925.

NEW REGULATIONS.

57. 1. No premises shall be licensed as a private hospital or nursing home if such premises are being used, or are intended to be used, for any other purpose ; nor

(1) Unless the buildings, including out-offices, (*a*) are in good repair and in a cleanly and wholesome condition ; (*b*) possess a sufficient supply of good water, free from liability to pollution ; (*c*) are, where sewerage is available, connected therewith ; (*d*) have within the curtilage such garden area or open space as may in the circumstances be reasonable.

(2) Unless there be provided (*a*) not less than 100 square feet floor space and 1200 cubic feet of free air-space for all infectious and serious operation cases, and not less than 75 square feet and 800 cubic feet of free air space for all other cases ; (*b*) adequate accommodation for nursing and attendants separate from the accommodation for patients ; (*c*) water-closets in the proportion of 1 to every 15 beds for patients, or, when sewerage is not available, pail-closets in the proportion of 1 to every 8 such beds ; (*d*) where the number of beds for patients exceeds 10, separate closet accommodation for the staff in the same proportion as in par. (*c*) hereof ; (*e*) upon every floor upon which patients will be accommodated, an approved slop-sink or " sluice " with water-tap, flushing cistern, flushing rim, and hot and cold water laid on, and arrangements for the satisfactory disposal of sewage therefrom ; (*f*) separate closet accommodation for any native or natives resident or employed on the premises ; (*g*) slipper-baths with hot and cold water laid on in the proportion of 1 bath for every 15 beds for patients, and, where the number of such beds exceed 15, separate bath accommodation for the staff, no closet or slop-sink or " sluice " to be constructed or permitted to remain in any bathroom ; (*h*) a suitable outside room in connexion with such private hospital or nursing home for use as a mortuary chamber.

2. No licensee of a private hospital or nursing home shall fail to display prominently on the door of each room intended for the accommodation of patients the number permissible in such room in terms of Subsection 1 (2) hereof.

58. No licensee of a private hospital or nursing home shall himself or by his servant or agent contravene or fail to comply with or to maintain any of the conditions, provisions, or requirements specified in by-law 57 hereof.

"SMALARINA" IN MALARIA.

To the Editor of THE LANCET.

SIR,—Prof. Cremonese's monograph was not unknown to us, but we must confess to some difficulty in following his pathology and in admitting some of his suppositions. The patients of whom we wrote, when placed on quinine and arsenic treatment, made the *usual* progress—no worse, no better, than the numerous patients suffering from malaria admitted to the Hospital for Tropical Diseases during the past several years. These patients appear to us to afford adequate control for the purpose of clinical judgment. " Smalarina " may or may not be of use as *an aid* to quinine ; our few cases were insufficient perhaps wherefrom to judge, but we did not find any beneficial result from its use.

Anyone interested in this subject might refer to " Smalarina Cremonese " published by the Bureau pour l'Encouragement a l'Emploi de la Quinine, Amsterdam.—We are, Sir, yours faithfully,

G. C. LOW.
A. L. GREGG.
Brook-street, Grosvenor-square, W., Sept. 29th, 1925.

PERSISTENT DIARRHŒA IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 26th Dr. H. de Carle Woodcock draws attention to the persistent diarrhœa which is such a serious complication of phthisis. Apart from actual tuberculous enteritis, I believe that the usual cause is the achlorhydria which is a very frequent sequel to phthisis. Permin[1] gave test-meals in 658 cases and found that free hydrochloric acid was absent in 23 per cent. in the " first stage," 34 per cent. in the " second stage," 47 per cent. in the " third stage," and in 75 per cent. of those who died within six months of the examination. It is a familiar fact that achlorhydria is the most common cause of chronic and recurrent diarrhœa in non-tuberculous patients, and that this can be rapidly and completely cured by the use of hydrochloric acid. Similarly, the rational treatment of the diarrhœa of phthisis is to administer the acid in adequate doses. The large dose required in such conditions as Addison's anæmia is unnecessary. As a rule, between 30 and 60 minims taken with each meal is sufficient to control the diarrhœa ; this can be given as a medicine in 2 oz. of water, or more agreeably as a beverage in a glass of water with the addition of sugar and the juice of an orange or a lemon.

I am, Sir, yours faithfully,
ARTHUR F. HURST.
New Lodge Clinic, Windsor Forest, Sept. 28th, 1925.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: PROPOSED NEW CHARTER.

To the Editor of THE LANCET.

SIR,—The annual meeting of Fellows and Members on Nov. 19th next will be one of most unusual interest, as the College Council has decided to lay before it in their annual report the exact terms of the petition and of the proposed new charter which the said Council intends to lay before H.M. Privy Council at a date unpublished. I presume that this date will be subsequent to Nov. 19th, so that the Fellows and Members assembled on Nov. 19th can give the Council their views on the suggested admission of women to the same status as men, whether Fellows, Members, or Licentiates in Dental Surgery, and on other innovations contained in the new charter.

My Society will present to the meeting on Nov. 19th a resolution suggesting that advantage be taken to insert a clause giving Members direct representation on the Council of the College. This will, once for all, restore to the Members the position of which they were robbed by the iniquitous charter of 1843. Presidents of the College have expressed regret, more than once, that it is only by obtaining a new charter such justice could be done, and that this is a very expensive process. Now is the time to prove if this remark was sincere. It will be an opportunity which Members and democratic Fellows have been waiting for since my Society was founded in 1894 ; indeed, since the establishment of the previous Association in 1884.

You may be sure there will be a *very large* attendance in the College on Nov. 19th next. The theatre was crammed to the utmost in November, 1908, when the proposed admission of women to the examinations of the College was debated and the results of a postcard vote made known. This proposal was, I might add, negatived by a majority, but the Council, heedless of this verdict, soon after permitted women to come up for examinations, but having no share whatever in the management of the College. This restriction the Council now proposes under the new charter to remove, *but not to take a poll* of the Fellows and Members.

---

[1] G. E. Permin: Internat. Beitr. z. Path. u. Ther. d. Ernährungsstör, I., Hft. 2.

This, however, is not the only "shot in our locker." We have been assured by the clerk of H.M. Privy Council that when the College Council's petition and proposed charter arrive before *his* Council, "an opportunity will be afforded to persons interested to bring a counter-petition." My Society will not fail to do so, and we are already taking steps to secure legal aid of the highest class to present ably our just cause and to support strongly a counter-petition on behalf of the 17,000 Members.

I am, Sir, yours faithfully,

SIDNEY C. LAWRENCE, M.R.C.S. Eng.,

Hon. Sec. of the Society of Members of the Royal College of Surgeons of England.

Sept. 21st, 1925.

RHEUMATISM AND RADIO-ACTIVE WATER.

To the Editor of THE LANCET.

SIR,—I have read with interest the figures given in the Ministry of Health's report on the prevalence of rheumatism. Treatment with radium emanations is the basis of successful treatment at all the famous spas in the world, and I personally consider that an immediate investigation into the possibilities of a national treatment of rheumatic patients by radio-active water would be of more practical value than the issuing of reports. Radio-active waters in these days are easy to produce; in fact, British manufacturers have now achieved the means of producing a water in the ordinary household which is considerably more potent in radio-activity than those of any of the continental spas and answering to the severest tests of the Curie Institute of France.

I am, Sir, yours faithfully,

E. DUNBAR TOWNROE, M.R.C.S.Eng., D.P.H.

Sloane-street, S.W., Sept. 23rd, 1925.

LUMINAL AND THE TREATMENT OF EPILEPTIC FITS OCCURRING AT ADOLESCENCE.

To the Editor of THE LANCET.

SIR,—The outlook of young people who have led healthy lives till they reach the age of early manhood or womanhood, and who then start having epileptic fits has been little improved by the wholesale drugging and dulling effects of maximum doses of bromides with attendant gastric disturbances. The trial of luminal in such cases seems indicated from the accumulating evidence, and the following two cases of epileptic fits occurring at adolescence may be of clinical interest.

Mr. K. I., aged 28, healthy history till age of 18, started having fits, at first of mild character, occurring once or twice a week. The severity and number of the fits increased till they became of daily occurrence, more especially during the early part of the morning. He was put on maximum doses of bromide, which did not, however, check the fits. He became very morose and depressed. On Dec. 28th, 1924, he was started on luminal, $1\frac{1}{2}$ gr., twice daily. He has had no fits since that date, and except for feeling a little drowsy for the first few days he now leads a normal existence, and is in fact a different man.

Miss V. M., aged 27, a sport-loving girl, did war work and had a nervous breakdown owing to strain. A legacy of typical epileptic fits was the sequel. These fits were more frequent and severe just before her menstrual flow every month, the latter becoming irregular. She became very apathetic and dull. Bromide in maximum doses combined with salt-free diet had no effect on the fits. Four months ago she was given luminal, $1\frac{1}{2}$ gr., twice daily; a fortnight after she had a slight "giddy turn" just when her menstrual period started, since when she has had no return of fits, and now is able to take interest in her work.

The similarity of age and onset of the above cases and the cessation of fits with luminal and the absence of after-effects would seem to make the more extensive use of this drug in similar cases worthy of trial, more especially in general practice.

I am, Sir, yours faithfully,

O. G. MISQUITH, M.A. Camb., M.R.C.S. Eng.

Chandler's Ford, near Southampton, Sept. 26th, 1925.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—Will you allow us through the columns of THE LANCET to disclaim all responsibility for paragraphs which have appeared in the public local press concerning us? Not only have such references been unsought by us, but they have caused us great distress, and have in every way been actively opposed by us.—We are, Sir, yours faithfully,

D. JUSTIN DAVIES.
Leicester, Sept. 28th, 1925. LUCY S. DAVIES.

THE DENTAL EXHIBITION.

THE International Exhibition, held at the Imperial Institute, South Kensington, from Sept. 28th to Oct. 2nd, again reflects the mechanical ingenuity which has been applied to dentistry. It is hardly the fault of inventors that striking novelties are far to seek amongst the maze of machines, appliances, and preparations.

The Pepsodent Toothpaste Company, of 42, Southwark Bridge-road, S.E. 1, show their Decoater tooth-brush, which is smaller and more efficient than most popular models; but the design of tooth-brushes is worth far more thought than has been given to it. Amongst tooth-pastes shown are the well-known Kolynos, Euthymol, and Crown brands. Each has undoubted merits which hardly require recapitulation; amongst those of the last is said to be a taste of fruit which makes its use less irksome to ladies and children. There is also exhibited a French dentifrice called Sanogyl, which is used in pyorrhœa and contains novarsenobenzol. Its virtue is supposed to lie in action against specific spirochætes causing pyorrhœa.

Local anæsthetics naturally receive much prominence. W. R. Black, of Vere-street, Birmingham, shows a new preparation called Isocaine, in addition to his well-known product Nopaine. Isocaine is said to be seven times less toxic than cocaine, without being irritant. C. J. Plucknett and Co., of 29, Poland-street, W. 1, exhibit their Sanpeine, which has no cocaine in it, and the Amalgamated Dental Co. have a cocaine preparation called Antipain, which has been in use for ten years. Similarly well established is Patterson's Local Anæsthetic, of which steadily increasing sales are reported by the Palatine Dental Manufacturing Co., of 5, High-street, Manchester, and Anodoon, 20 years old, which is prepared by the Glasgow Dental Depôt, Ltd. This firm also shows useful flasks and flask clamps and a satisfactory form of articulator. The Hoffman-La Roche Chemical Works, Idol-lane, E.C. 3, strongly recommend their sedative, analgesic and hypnotic, Allonal; it is a barbituric acid derivative, intended to be given before and after operations.

Several firms, including the Palatine Dental Manufacturing Co., exhibit a new preparation named Nugum, which is "a plastic coral for perfectly natural dentures," and can be vulcanised like rubber in an ordinary vulcaniser. Of artificial teeth there are excellent displays by many firms, including the Dental Manufacturing Co., Courtin and the International Tooth Co., and the S. S. White Co.—all of London. Dentures of gold-covered vulcanite are shown by the Gold-Sealed Denture Process, Ltd., 9, Golden-square, W. 1. Many firms show beautifully finished instruments, amongst which may be mentioned the Rayway Dental Unit of Norman Rayne, Ltd., 48, New Cavendish-street, W. 1. Gould and Co., of Agol House, Mount Pleasant, Liverpool, show their Agol equipment and preparations, and the Amalgamated Dental Co. have efficient gas-and-oxygen apparatus, and a new adjustable spot-lamp. They also exhibit their excellent Solila hypodermic needles, made of rustless steel, and a new small adjustable gag. Cottrell and Co., of 15, Charlotte-street, W. 1, demonstrate an automatic rubber packing and wax dispersing apparatus and Dr. Oberlander's process of enamelling dentures.

Baillière, Tindall and Cox, who publish the *Dental Surgeon*, display books on dentistry; so also does Henry Kimpton, of 263, High Holborn, W.C. 1. Amongst smaller items are the Lysepticol mouth-wash tablets, of the Midland Dental Manufacturing Co., Birmingham; the chlorine antiseptic, Chloramine, of W. R. Black, and the new iodine solution, Presoiod, sold by Lionel Cooper, 14, Henrietta-street, W.C. 2. A small cheap sterilising lamp, burning solid fuel, which is made by Francis Lepper and Co., of 55, Great Marlborough-street, W. 1, has found many buyers. Last, but far from least in helpfulness, is the glass of hot virolised milk provided for visitors.

Medical News.

Royal College of Surgeons of England.—Demonstrations of specimens in the Museum will be given at 5 P.M. during October and November in the theatre of the College in Lincoln's Inn-fields, as follows: By Prof. Sir Arthur Keith: Friday, Oct. 16th, Specimens Illustrating the Pathological Anatomy of Acromegaly; Oct. 23rd, Preparations and Models to Illustrate the Mechanism of the Internal Ear; Oct. 30th, Preparations and Dissections to Illustrate the Evolution of the Human Mechanism of Hearing; Nov. 6th, Exhibition of Microscopical Preparations made from Recent Cases of Intestinal Stasis. By Mr. Shattock: Monday, Oct. 19th, Lips and Tongue; Oct. 26th, Cysts; Nov. 2nd, Some Bone Tumours. The demonstrations are open to advanced students and medical practitioners.

Chelsea Clinical Society.—The annual dinner of the society will be held at the Café Royal, Regent-street, W., on Tuesday, Oct. 20th, at 7.30 P.M.

Pharmaceutical Society of Great Britain.—On the occasion of the opening of the eighty-fourth session of the School of Pharmacy at 17, Bloomsbury-square, London, W.C., on Wednesday, Oct. 7th, Prof. Winifred C. Cullis will deliver the inaugural sessional address, and the Pereira medal will be presented.

St. Thomas's Hospital Medical School.—The old students' dinner will take place at the Hotel Victoria, Northumberland-avenue, W.C., on Friday, Oct. 30th, at 7.30 P.M. The chair will be taken by Mr. Samuel Osborn. On Monday, Nov. 2nd, at noon, H.R.H. the Duke of York will lay the foundation-stone of the College House extension. The ground and first floors of this building, which is being erected opposite the hospital in Lambeth Palace-road, will house the students' club premises, whilst the upper four floors will provide resident accommodation for some 60 students, in addition to members of the resident staff of the hospital.—The following scholarships have been awarded by the school: Entrance Arts Scholarships, 1925 (value £50), Mr. A. G. Sanders, St. Paul's School, West Kensington; (value £50), Mr. J. F. E. Bloss, Monkton Combe, Bath. Entrance Science Scholarships, 1925 (value £150), Mr. K. M. Robertson, Eltham College; (value £60), Mr. D. O. Clark, Eltham College. The William Tite Scholarship, 1925 (value £25), Mr. A. M. Easton, Whitgift Grammar School, Croydon.

Post-Graduate Course at St. Mary's Hospital. A series of lectures will be given at St. Mary's Hospital over the present week-end, starting on Saturday, Oct. 3rd at 11 A.M. The course will be open to all practitioners without fee, and the following lectures will be given: Saturday, 11 A.M., Mr. C. W. G. Bryan: The Management of Common Forms of Urinary Obstruction; noon, Mr. S. Maynard Smith: The Differential Diagnosis of Gall-Stones; 2.30 P.M., Mr. T. G. Stevens: Hæmorrhagic Ovarian Cysts, a Common Cause of Pelvic Pain; 3.45 P.M., Dr. C. M. Wilson: The Patient's Point of View in Treatment (with cases). On Sunday, 11 A.M., Mr. Zachary Cope: Minor Surgery in General Practice; noon, Prof. B. J. Collingwood: Some Applications of Physiology in Practice. On Monday, 10 A.M., Mr. Warren Low: Clinical Aspects of Malignant Disease of the Colon; 10.45 A.M., Prof. Langmead: Overlooked Causes of Fever in Children; noon, Mr. Aleck W. Bourne: Clinical Types in Gynæcology; 2.30 P.M., Sir William Willcox: Chronic Toxæmia, its Recognition and Treatment; 3.45 P.M., Mr. Duncan Fitzwilliams: Lecture and Demonstrations on Cancer of the Breast.

Caledonian Medical Society.—The fortieth annual meeting and dinner of this society will be held at the Central Station Hotel, Glasgow, on Friday, Oct. 9th, under the presidency of Dr. Neil T. Kerr, of Hartwood.

Hunterian Society.—The presidential address to the society will be given by Dr. F. Howard Humphris at a dinner meeting in Simpson's Restaurant, Cheapside, E.C. 2, on the subject of Light. The date of the meeting is Oct. 19th, at 7.30 P.M., and not Oct. 12th as announced in the society's calendar.

Charing Cross Hospital Medical School.—The annual dinner of past and present students will be held in Gatti's Restaurant, Strand (entrance, King William-street), on Monday, Oct. 5th, at 7 for 7.30 P.M. Dr. W. J. Fenton will be in the chair. The distribution of prizes to students by Sir Herbert Waterhouse will take place on the afternoon of the same day at 3.30 in the out-patients' hall of the hospital.

Harveian Society of London.—The subject selected for the Buckston Browne prize is the Ætiology of High Blood Pressure and of the Respiratory Phenomena Associated with High Blood Pressure and Chronic Nephritis. The prize consists of a medal, together with the sum of £50, and it is open for competition to any member of the medical profession registered in the British Isles or Dominions, under 45 years of age. Further particulars may be seen in our advertisement columns.

British Science Guild.—The first annual Norman Lockyer Lecture, established by the British Science Guild as a means of periodically directing the attention of the public to the influence of science upon human progress, will be given by Sir Oliver Lodge, F.R.S., on the Link Between Matter and Matter, and the lecture will be held on Monday, Nov. 16th, at 4 P.M., in the Hall of the Goldsmiths' Company (by permission of the Master and Court of Assistants of the Company), Lord Askwith, President of the Guild, in the chair. Tickets of admission may be obtained on application to the Secretary, British Science Guild, 6, John-street, Adelphi, London, W.C. 2.

Medical Defence Union.—The annual general meeting of the Medical Defence Union was held at 49, Bedford-square, London, on Sept. 25th. Mr. Walter G. Spencer, the President, in moving the adoption of the annual report of the Council for the year 1924–25, said that the report was certainly one of the most satisfactory and successful which had ever been issued. The increase of members during the past two or three years was quite unprecedented, and no doubt this was largely due to the fact that the teachers in the medical schools were now making a point of telling the newly-qualified to join one or other of the defence societies. Mr. F. C. Larkin, Mr. D. Drew, and Dr. V. A. Jaynes were unanimously re-elected members of the Council.

National Hospital for the Paralysed and Epileptic.—A post-graduate course will be held at the Hospital, Queen-square, Bloomsbury, W.C., from Oct. 5th to Nov. 27th. The course will consist of the following subjects: (1) Out-patient clinics, Mondays, Tuesdays, Thursdays, and Fridays, 2 P.M.; (2) clinical lectures and demonstrations on the same days at 3.30 P.M.; (3) lectures on the anatomy and physiology of the nervous system (if sufficient applicants), Mondays, 12 noon; (4) lectures on the pathology of the nervous system, Thursdays, 12 noon; (5) clinical demonstrations on methods of examination (if sufficient applicants), Tuesdays and Fridays, 10 A.M. A syllabus and further particulars of the course may be obtained from the secretary of the hospital.

Royal Institute of Public Health.—A course of lectures on Preventable Diseases will be delivered in the Lecture Hall of the Institute, 37, Russell-square, London, W.C. 1, at 4 P.M., on Wednesdays from Oct. 14th to Dec. 16th. Colonel S. Lyle Cummins, David Davies Professor of Tuberculosis, University College of South Wales and Monmouth, will deliver the first lecture on the Prevention and Arrest of Tuberculosis, on Oct. 14th, with Lieut.-Colonel Cuthbert James, M.P., in the chair. Whilst these lectures are intended primarily for the Fellows and Members of the Institute, all others, men and women, interested in medico-sociological problems are cordially invited to attend. The Harben Lectures will be given by Prof. J. C. G. Ledingham, F.R.S., on Current Problems in Bacteriology and Immunology, and their bearing on Public Health Effort, on Dec. 9th, 10th, and 11th, at 5 P.M. A copy of the syllabus may be obtained from Dr. E. W. Hope or Dr. T. N. Kelynack, hon. secretaries, at the Institute.

THE winter session of the James Mackenzie Institute for Clinical Research, St. Andrews, will open on Tuesday, Oct. 6th, at 4 P.M.

THE resignation is reported of Sir Henry Gray from the chief surgeoncy of the Royal Victoria Hospital, Montreal.

Dr. Basil Graves, who has recently been appointed surgeon to the St. Paul's Eye Hospital, Liverpool, has been given leave to enable him to deliver a series of advanced clinical courses on Special Methods and Principles of Technique employed in Microscopy of the Living Eye, at the Bellevue Department of Ophthalmology, New York University.

QUEEN'S UNIVERSITY (BELFAST) CLUB, LONDON.—The annual business meeting and autumn dinner of the club will be held at 7 and 8 P.M., respectively, on Thursday, Oct. 15th, at the Connaught Rooms, Great Queen-street, W.C. 2. Members of the University wishing to join the club should communicate with the Honorary Secretaries at 132, Harley-street, W.

CONFERENCE ON LIBRARIES.—The Conference held by the Association of Special Libraries and Information Bureaux at Oxford was attended by over 200 delegates, representing many countries. It was stated that there are over 25,000 scientific periodicals, and it is obvious that organisation is needed. Miss A. L. Lawrence, of the British Medical Association, discussed the coördination of medical information, and Dr. Kentish Wright, of the Ministry of Health, gave particulars of the intelligence service at the Ministry.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY. Some three or four years ago Whitehaven Castle, one of the seats of the Earl of Lonsdale, was bought privately and, together with £20,000 to cover the cost of alterations, presented to the governors of the Whitehaven and West Cumberland Infirmary. The alterations are now nearly completed, and the new hospital will shortly be opened by Princess Mary. When Sir John Lowther bought the building in 1675 from Sir George Fletcher it was called Flatt House, but was subsequently re-edified and re-named Whitehaven Castle.

ROYAL VICTORIA HOSPITAL, BELFAST.—It is estimated that the large extensions now in progress, portions of which are already completed and in working order, will cost approximately £125,000. Twenty years ago the expenditure of the hospital, which is the medical school of the University, was £14,000; last year it was £53,000; this year it will be £63,000. The income is now inadequate to the extent of over £10,000, and an offer has been made of a contribution of £1000 conditional upon nine similar contributions. The extensions comprise three additional wards to hold 80 beds, a six-floored nurses' home, which will house the whole of the nursing staff, and two new clinical theatres. An entire floor is being adapted as a dental clinic.

Appointments.

CRAIB, M., M.D., Ch.B., has been appointed Resident Medical Officer for Frere Hospital, East London, South Africa.

GRAVES, B., M.R.C.S., L.R.C.P. Lond., Surgeon to St. Paul's Eye Hospital, Liverpool.

O'CONNOR, BRYAN V., M.R.C.S. Eng., L.R.C.P. Lond., Resident Medical Officer, General Hospital, Jersey.

PLATT, H., M.D., M.S. Lond., F.R.C.S. Eng., Consulting Orthopædic Surgeon to the Devonshire Hospital, Buxton.

TROUP, G., M.D. Aberd., D.P.H., Medical Superintendent, Willesden Municipal Hospital.

Ashton-under-Lyne Board of Guardians: WHITE, L., M.R.C.S., L.R.C.P. Lond., Medical Superintendent, non-resident; RALPHS, F. G., M.B., Ch.B. Manch., Surgeon, non-resident; and EVANS, G. I., Assistant Medical Officer, resident.

Vacancies.

For further information refer to the advertisement columns.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—H.S. and Asst. H.P. Each at rate of £100. Also Asst. S. 50 guineas.

Bermondsey Infirmary, Lower-road, Rotherhithe, S.E.—Jun. Asst. M.O. £400.

Birmingham, City Mental Hospital.—Asst. M.O. £350.

Brighton, Royal Sussex County Hospital.—H.S. £150. Also Surg. Clin. Asst.

Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsthetist. At rate of £130.

Cardiff Royal Infirmary.—Ophth. H.S. At rate of £50.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Out-patient Registrar.

Delhi, India, Lady Hardinge Medical College and Hospital.—Radiologist. Rs.750.

Holland County and Boston Borough Education Committee.—Dent. S. £450.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. At rate of £50.

Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.—H.P. and H.S. At rate of £100 and £75 respectively.

Hull City Education Committee.—Asst. Sch. M.O. £600.

Leicester Royal Infirmary.—Second Res. Anæsthetist. At rate of £200.

Lucknow University.—Prof. of Surgery. Rs.1200–50–1400.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Two Hon. Phys.

Manchester Royal Infirmary.—Res. M.O. and Asst. M.O. At rate of £200 and £100 respectively.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Res. M.O. £200.

Northern Ireland Ministry of Home Affairs.—Med. Inspector. £500.

Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.

Portsmouth Royal Hospital.—Cas. O. At rate of £100.

Renfrew County.—Asst. Tub. O. £600.

Royal Chest Hospital, City-road, E.C.—Res. M.O. and H.P. At rate of £150 and £100 respectively. Also Phys. to Outpatients. £50.

Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £200.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Registrar. 100 guineas.

Royal Northern Hospital, Holloway, N.—H.P. and H.S. At rate of £70. Also P.

Seychelles Government.—Asst. M.O. and Res. S. Rs.6500.

Southend-on-Sea County Borough.—Asst. M.O. £600.

Stockport Infirmary.—Sen. H.S. £250.

Winchester, Royal Hampshire County Hospital.—H.P. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments for Certifying Factory Surgeons: Looe (Cornwall), Shrewsbury (Salop). and Wylam-on-Tyne (Northumberland).

Births, Marriages, and Deaths.

BIRTHS.

ANDERSON.—On Sept. 24th, at Albyn-terrace, Aberdeen, the wife of William Anderson, F.R.C.S., of a son.

CROSSMAN.—On Sept. 16th, the wife of Dr. Francis Ward Crossman, Whites Hill, Hambrook, Glos., of a son.

DINGLEY.—On Sept. 25th, the wife of J. R. Dingley, M.B., B.S., Robertsbridge, Sussex, of a daughter.

MOLLAN.—On Sept. 23rd, at Staunton Lodge, Gosport, the wife of Captain F. R. H. Mollan, M.C., R.A.M.C., of a son.

VERCOE.—On Sept. 24th, at Old Court, Ealing, the wife of R. H. Vercoe, D.P.H., M.O.H. Chelmsford, of a son.

MARRIAGES.

MCCREA—WILLOCK.—On Sept. 25th, quietly, at Ottery St. Mary, Devon, Edward D'Arcy McCrea, F.R.C.S.I., M.Ch. Dub., to Edith Florence Willock, F.R.C.S.I., only daughter of Mr. and Mrs. W. A. Willock, Green Bushes, Budleigh Salterton.

MACKINNON—BAGNALL.—On Sept. 24th, at St. Mary's, Hammersmith-road, West Kensington, Archibald Donald Mackinnon, C.M.G., M.D., Kyleakin, Isle of Skye, to Sylvia Joan, widow of Lieut.-Colonel C. E. Bagnall.

DEATHS.

BROWN.—On Sept. 26th, at Preston Park, Brighton, Thomas Lloyd Brown, M.R.C.S., of Stonecroft, Cuckfield.

DAVIES.—On Sept. 23rd, at East Cliff Cottage, Bournemouth, Dr. William Morriston Davies, aged 83.

FOX.—On Sept. 27th, at Bradford-street, Walsall, George Martin Fox, M.D., D.P.H., J.P., in his 61st year.

KIRKNESS.—On Sept. 19th, at The Haven, Pembury, Tunbridge Wells, suddenly, of pneumonia following influenza, William Ronald Kirkness, M.R.C.S., L.R.C.P., eldest son of the late William Kirkness, of Falmouth, and of Mrs. Kirkness, Haslemere, Surrey.

THOMAS.—On Sept. 25th, suddenly, Hugh Mortimer Thomas, M.R.C.S., L.R.C.P. Lond., Tower Hill, Fishguard, aged 52.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE DEATHS OF MERCHANT SEAMEN IN 1923.

BY W. E. HOME, M.D., B.SC., D.P.H.,
M.R.C.P. EDIN.,
FLEET SURGEON, R.N. (RETIRED).

THE deaths of merchant seamen in 1923 are recorded in the Board of Trade's "Return of the Shipping Casualties to and Deaths on Vessels Registered in the United Kingdom" recently issued. The figures tabulated below may be compared with those previously published [1] for 1921 and 1922, but there is added a line, "equivalent for a single death," which correlates the death-rate per 1000 with the number of persons on which the figures are based, showing by how much any individual death affects the rate per 1000 in any group, such as the Lascars. The total numbers of men serving amongst whom the deaths occurred is once again not given in the report, but has been kindly supplied to me by the Board of Trade. It is only approximate, but no more accurate information is available. The same method of compilation has been used as before and it is probable that the errors are roughly constant from year to year. The death-rate for 167,794 British seamen in 1923 was lower than in 1922, and also lower in each of the three groups—alcohol, diseases, and accidents. This year there were 35 suicides, 32 men were lost through drink, 188 by casualties to their ships, and 362 by disease. There were 50 deaths from pneumonia, 29 from tuberculosis (a decrease of 17), 25 from malaria, and 19 from enteric fever. The 55,935 Lascars form the next largest group in the mercantile marine, and their gross death-rate of 8·01 is higher than in 1922, the main increase being in deaths from disease. There were 17 suicides; none were lost through drink, but 135 in casualties to their ships (73 in the *Okara*). Fifty-six died of pneumonia and 42 of tubercle, to which diseases they are more susceptible as a group. They also suffered more through casualties to ships and accidents on board, particularly from falls down hatchways and "missing at sea," but much less from accidents on shore, in which drink is apt to play a part. Foreign seamen (11,262), a smaller group, suffer most from accidents on board, tubercle, and circulatory and digestive diseases. In the whole mercantile marine there were no deaths in 1923 from plague, which was rather a triumph; but there was an increase of 7 from beri-beri and 21 from pneumonia. There were 14 fewer from tubercle; cancer deaths were at the same rate in British and Lascar seamen, and there were fewer accidents. It must be remembered, however, that these death-rates are only approximate, and that periods of irregular employment increase accidents, but, owing to the method of preparation of this return, will lower the apparent death-rates. In sailing ships (2156 men) the fatal accident-rate was 14·2, against 2·7 in steam (five times as high), and there were no deaths from either alcohol or disease. In the Royal Navy in 1922 accidents, pneumonia, and tubercle were the chief causes of deaths, and there was less malaria, enteric fever, and circulatory system disease than amongst British merchant seamen. The relative ages in the two groups unfortunately cannot be compared.

In 1924 the Royal Sanitary Institute represented to the Ministry of Health and to the Board of Trade that this classification of diseases was antiquated and should be remodelled, and that the compilation of death statistics and the care of the health of the men of the merchant service should be given in charge to the Ministry of Health, as the Board of Trade was not specially organised for this duty. The Prime Minister stated in March, three months before this return appeared, that the Board of Trade was "in close touch with the Ministry of Health on all matters affecting the health of seamen." Evidence of the effect of this "close touch" is not apparent in this return. The Board of Trade may have been in intimate association with the Ministry's medical advisers, but has presumably been unable to assimilate the wealth of scientific information they have offered. Tuberculosis is still not classified as an infectious disease, and the Board has not yet learned that figures of deaths are of little practical interest unless accompanied by a statement of the numbers of the population amongst whom they occurred. The shortest of conferences with the Ministry should have conveyed this axiom. The report is intended to "furnish an approximate basis for estimating the variations in the extent of the risks from period to period," but how can anybody estimate the variations if he is merely told that in one year there were 946 deaths and 860 in another? It is necessary to know how many British seamen there were in the service in each of these years. The President of the Board of Trade said in March that the Board had under consideration the

[1] THE LANCET, 1924, ii., 981; 1925, i., 783.

modifying of the classification of diseases in the statistics it issues of the deaths of seamen, yet it has evidently decided to adhere to that originated by the great William Cullen (Professor of Medicine in Edinburgh from 1755 to 1790), which, since the re-birth of medicine in the "seventies" of last century, has been deserted by all the best authorities and by most Government departments. If this organisation of laymen has the self-confidence to stand, with no medical officer's signature to support it, against all educated medical opinion as regards classification of disease, may it not also have its own private standards in preventive medicine? It is to be hoped that is not why Lascar seamen go on having three times as many deaths from tubercle as have British seamen, who, under the Board of Trade, have 60 per cent. more statutory space in ships. The Board of Trade appears to be recognised by the Prime Minister as in charge of the health of seamen. It does provide for the treatment of their diseases and for drugs to heal them when sick, though it has resigned the treatment of their venereal diseases to the Ministry of Health. But the Board publishes no annual report on the health of the 250,000 merchant seamen in its charge, and can anyone believe that it takes its responsibility seriously? That responsibility should undoubtedly be transferred, as the Royal Sanitary Institute suggested last year, to the Ministry of Health.

TWO YEARS' WORK IN IRAQ.

Report of Inspector-General of Health Services.

The Inspector-General of Health Services in Iraq has issued from Baghdad his report for 1923 and 1924, in which he claims that in spite of many difficulties satisfactory progress has been made by his department. Schemes for making local authorities responsible for their hospitals and health work have fortunately been abandoned, and the central government pays for the upkeep of the whole service, which ensures that there shall be none of the local weak links whose inefficiency may prove fatal in an epidemic. At the end of 1923 the civil health service maintained 1170 beds; there are now 18 hospitals and 32 dispensaries, and the Royal Hospital at Baghdad, with 250 beds and a large out-patient department, has become a most valuable medical centre with excellent facilities for treatment and teaching. Other hospitals are making progress and the new Maude Memorial Hospital at Basrah, which will have 120 beds, will be the best for its size in the country. The authorities intend gradually to build up a service staffed by Iraqi doctors, but it is extremely difficult to get candidates, and the local doctors do not take kindly to travel amongst the tribes, which is a most valuable part of the work done by British surgeons. Three-quarters of the population of 3,000,000 are tribesmen and the usefulness of specialists at Baghdad depends on the persuasive ability of outlying workers. This nomadic character of the people makes it hard to secure vital statistics, and these can only be given for the great towns. Here the figures for births are unreliable because the people neglect notification on principle, remembering that the Turkish officials used the information they thus obtained for conscription for the army.

Infectious Diseases.

Under Turkish régime epidemics were controlled by the inefficiency of transport. Now the railways which connect Baghdad with Basrah, Shergat (70 miles south of Mosul), and Khanaqin, and the motor routes to Damascus, Beirout, and Teheran enable diseases to spread up and down the country in a day or two. Iraq is full of holy places and the pilgrims are an additional problem, since for political reasons it is not always possible to stop their movements. For example, during an epidemic of cholera at Karbala in 1923 90,000 pilgrims came to the town; but although they could not be stopped nearly all were inoculated. In the 1923 cholera epidemic roughly 300,000 inoculations were done by the Service—vaccine had to be prepared in Baghdad—and their success "affords a very definite proof of their value." This epidemic showed itself first at Abadan in Persia, 30 miles below Basrah, and here there were 961 cases with 911 deaths in about six weeks, out of a population of 6000. Then it spread to Basrah, which has over 50,000 inhabitants; but the preventive measures adopted before the disease had got a grip on the town reduced the number of cases to 605; there were 436 deaths. The most urgent need was to save Baghdad from an epidemic, and by means of traffic control, inoculation, and the establishment of segregation camps this was achieved; in the whole of Iraq there were only 1640 cases with 1100 deaths.

Plague.—There were 787 reported cases of plague in Iraq in 1923 and 523 in 1924. The epidemic in these two years was not exceptional, as the disease appears yearly in Baghdad and Basrah, and sporadically elsewhere. It is impossible to ensure that plague-infected rats will not occasionally gain access to river boats, and the railway presents a further problem which is apparently insoluble. The carriage of grain by rail is essential for the commerce of the country, and whatever precautions may be taken for cleansing railway stock it is obviously impossible to prevent rats gaining access to wagons at some part of the loading or shunting operations or during their passage up or down the line. The country is therefore faced each year with the possibility of local epidemics. The disastrous outbreak in 1918 at Amara, where 500 cases occurred in a population of 12,000, may be taken as an example. The possibility of similar epidemics is greatly increased by the extension of the railway from Baghdad to Kirkuk and its proposed extension to Mosul. The value of plague vaccine as a protective measure and in reducing case-mortality is definitely shown in the report; 300,000 inoculations have been given in Baghdad during the last six years without accidents; although the reaction is severe inoculation is willingly accepted by all classes except the most ignorant, and the M.O.H. of Baghdad has strongly urged that it be made compulsory whenever plague appears in a town. It is doubtful, however, if this could be enforced by the Iraq Government.

During the cold wet winter seasons of 1923 and 1924 there have been small epidemics of pneumonic plague in which the infection occurred from mouth to mouth or by contact with corpses. These outbreaks are especially interesting in view of the opinion, now gaining ground, that pneumonic plague differs from bubonic plague through the action of a symbiotic organism such as the bacillus of pneumonia. The two forms of plague occurred together, and "their origin was undoubtedly from bubonic plague cases in Baghdad, the virulence of which had become modified by some factor connected with the climatic conditions." The mortality of the pneumonic variety was 100 per cent. The bubonic mortality varies; it was 85·7 per cent. in 1921 and 55·1 per cent. in 1923.

Small-pox is endemic amongst the tribes and occasionally becomes epidemic in the towns. Vaccination is compulsory, but although even the wildest tribes recognise its value more than is done in England, the law is hard to enforce owing to the carelessness of the people and inaccurate birth notification. Over 80,000 vaccinations were performed in 1923 and now eight travelling vaccinators have been appointed. *Measles* is always present in some part of the country; in 1924 there were 1347 reported cases and this is considered an epidemic year. There have been only a few cases of *typhus*, and these are attributable to pilgrim traffic from Persia, where the disease is prevalent. *Enteric group diseases* occurring in Iraq are fortunately not usually very severe; 158 cases were reported in 1923 and 134 in 1924. A progressive increase in the number of cases of *tuberculosis* is reported yearly. There were 178 in 1921, 398 in 1922, 503 in 1923, and 819 in 1924. The general opinion is that the increase is only apparent and is due to better notification of cases and to increased confidence in medical institutions, but it is also possible that a proportion of the increase is actual and is due to a lower standard of living now that the population have lost the free flow of money that came to them from the British Government during and after the war, and are resuming their harder but more normal existence. *Anthrax* from time to time occasions epidemics of varying severity amongst sheep and cattle, but is comparatively uncommon amongst the Iraqi who live in close contact with them. Malignant pustule has a stereotyped treatment amongst the tribes. The carbuncle is surrounded by a wall of dough, the centre of which is filled with gunpowder and lighted; the process is repeated until the burning gunpowder produces pain, after which the burned area is left to heal. This treatment is often efficacious, the disease in Iraq being of low virulence.

Schistosomiasis.—Bilharzia is probably the commonest disease in Iraq, and about 90 per cent. of the population of the southern half of the country live in localities where they are exposed to infection. In these areas the incidence is from 20–100 per cent., and in some places to pass blood in the urine is considered normal. Till complications supervene the inhabitants will not submit to treatment, and even then they are indifferent and think the benefits of a long course of antimony injections not worth the trouble. Schemes for eradicating the water-snail which is the intermediate host involve the temporary closing of canals and consequent loss of crops, and it is doubtful if they could be carried through. *Malaria* roughly corresponds in distribution to bilharzia—that is, it favours the marshy and irrigated areas. The health service annually treats some 45,000 persons, but these are only a small fraction of those affected, and the treatment can seldom be more than palliative. Perhaps 20 per cent. of the population of Iraq (600,000 persons) require treatment, and about 20,000 lb. of quinine would be needed annually for merely palliative treatment. This would involve an expenditure of Rs.600,000 per annum, which is at present out of the question ; in 1923 and 1924 a total of 6900 lb. distributed was the most that could be paid for. Radical antimalarial measures are expensive, and large drainage operations would deprive many of the population of their means of livelihood (e.g., rice and date cultivation). Further activities against the disease must therefore wait until the Government can afford to distribute more quinine. The report gives an interesting account of an apparent epidemic of malaria in 1924 which was possibly an infectious fever of the nature of influenza which determined or aggravated attacks of malaria. *Leprosy* is widely spread throughout the country, but probably the total number of cases in Iraq is not more than 300. Treated as outcasts amongst the tribes, they drift into the large towns ; it is rarely possible to trace any given case to any other. The establishment of a leper colony presents almost insurmountable difficulties—financial, tribal, racial, and religious.

The Work of Health Service Institutions.

Although a holy country to a large section of the Mohammedan world, Iraq does not attract charitable endeavour, in contrast to Palestine, where two-thirds of the lavish medical facilities owe their existence to charity. Practically all the public hospitals and dispensaries have to be maintained by the State. The work is limited by lack of money, but in two years there have been nearly two million out-patient attendances, and in 1924 15,500 cases were treated in hospitals. The care of the aged, infirm, and incurable is impossible. The first-class hospitals at Baghdad, Basrah, and Mosul perform between 2000 and 3000 major operations yearly, but such operations are practically limited to hospitals in charge of British surgeons. Two ophthalmic surgeons are employed—at Basrah and Baghdad—and a great deal of work is being done ; but the field is enormous. About 80 per cent. of the population of Baghdad suffers from trachoma, and as a charge of 4 annas a week reduces attendances at clinics by three-quarters, it is again clear that the Government will have to pay if things are to improve. X ray facilities are provided in the three great towns ; there is a chemical department at Baghdad, and a very competent pathologist in charge of a laboratory there, who also supervises the antirabic and vaccine lymph institutions. Rabies is widespread in Iraq, and cases of dog, jackal, and wolf bites present themselves in a steady stream. The report gives details of a series of interesting cases showing a considerable measure of success in treatment.

Venereal diseases are extremely common amongst all classes, but the manifestations are milder than in Europeans. Of 280 registered prostitutes examined at Basrah 270 showed infection ; brothels are mainly under supervision and preventive measures are encouraged. *Opium-eating* is a well-established practice, especially in the centres of Persian influence, and opium-smoking is common at pilgrimage towns. The tribes use opium chiefly for medicinal purposes, but under Turkish and Persian influence the morphine habit is growing commoner in towns, and cocaine is taking hold of the educated classes.

Medical and Dental Practice.

With two exceptions all the private medical practitioners in the country have settled in the three great towns, where there are far too many of them. A huge influx of doctors comes from Syria, where many poorly qualified men are yearly turned out on a country which has an excess of them already. Turkey is closed to them, so they exploit Iraq. The consequence is that charlatanism and questionable practices are becoming increasingly rife, and that Iraqi doctors find it hard to live. There is as yet no Iraqi medical school. Dressers and hakims are perforce permitted to practise under nominal supervision in some areas, and more or less qualified dentists are allowed to practise with reservations. The country suffers from a lack of trained midwives ; but conditions are improving in the towns, and in most of the country districts there are one or two midwives who may be regarded as fairly clean in their methods. Unfortunately, in the East very few respectable women will take up this work, and of the middle-aged women available very few can read or write, and those who cannot are somewhat insusceptible to training.

MEDICAL MISSION CONFERENCE.

THE meeting of the Medical Mission Advisory Board of the Conference of British Missionary Societies at the Bible House, Queen Victoria-street, London, on Sept. 23rd, occupied most of its time in discussing the problems of passing on to the national churches the responsibility and support of mission hospitals, and also the question of the strict adherence to a high standard of nursing, especially in a country like China. Dr. Hugh H. Weir, medical secretary of the S.P.G., who acted as chairman, in initiating the discussion, said that hospitals should not be looked upon merely as humanitarian institutions or even as valuable instruments in bringing forward the Christian gospel, but as instruments for perpetuating the Incarnation. Their tone was therefore the all-important factor, and the primary question to be borne in mind was how far this was being created and how far it would be continued in other hands. Dealing with obstacles to be overcome, Dr. James L. Maxwell, general secretary of the China Medical Missionary Association, said that the financial ones could largely be met by further accommodation for paying patients, but that the question of qualified doctors was more difficult owing to the fact that there were now only seven or eight properly equipped Christian medical schools turning out some 20 men a year to supply the need of China's 300 mission hospitals. Dr. J. H. Cook, medical secretary of the C.M.S., speaking from his experience in Africa, emphasised the need of spiritual, intellectual, and social fitness of the native doctors before institutions could be handed over. The question raised by Mr. W. McAdam Eccles, F.R.C.S., as to how far foreign doctors could continue on the staff after the handing over of a hospital was not answered in the course of the discussion, while the problem which perplexed many, especially some of the women doctors from India, was the advisability of native doctors on the hospital staff also having a private practice. It was felt by many that this was not advisable. Dr. H. T. Chiang, a Chinese guest from Hankow, said that the time was not ripe for handing over hospitals to the Chinese Christian Church. He advocated Anglo-Chinese boards of management to turn the institutions into community hospitals, and the gradual reduction of grants-in-aid to provoke local responsibility. At the afternoon session the actual discussion was almost confined to the standard of nursing in China. Some pleaded that this was too high, too "Americanised," and was a bar to the preparation of sufficient nurses for the urgent needs of the country. It was evident, however, that the majority did not wish to see standards lowered, and as was pointed out, this was the express wish of the Chinese themselves, who formed to-day 75 per cent. of the membership of the Nursing Association of China.

REFUGEES IN MACEDONIA.

THE situation of refugees at Salonika is still serious. It is estimated that in this city alone there are 80,000 refugee widows and children, many thousands of whom are solely dependent on charity. The Government's allowance to them is 1 drachma (about ¾*d.*) per day, and bread costs 8 drachmas a loaf. In general town-dwellers are worse off than peasants in these unaccustomed conditions ; but those refugees who have been sent to outlying parts of Macedonia as agricultural tenants are in serious plight as they received their land too late to sow crops and the Government is not going to distribute grain for food as it did last year. Many crops have also failed through storms. At Salonika refugees are still crowded in mosques, schools, and warehouses. In the barracks a family of six or seven often occupies a floor space of 3 or 4 square yards. Many have been living like this for three years and are still wearing the remains of the clothes in which they arrived. Malaria is not so bad as last year, but in one camp there are 400 cases, and 150 cases of dysentery. The "Save the Children Fund" is the only organisation rationing the people in the Salonika area and is feeding some 9000 people there, but has to turn many away. Its milk stations are greatly appreciated and clothes are badly needed. In order to maintain and increase its services it urgently requires help.

TO CHIROPODISTS AND OTHERS.

THE Society of Chiropodists has reprinted[1] a series of lectures delivered by Mr. Lake, which cover an extensive area, and they should appeal to a wider public than that comprised by the Society. They would form, in fact, an admirable introduction to anyone starting to study medicine, or indeed to anyone interested in the progress of medical science. The development of bacteria, the principles of asepsis, and the causes and processes of disease are dealt with in a masterly manner. The more special articles on the mechanism of the foot and its deformities are of value as an introduction to this branch of orthopædics. But the lectures cover the field from the early history of man to the latest advances of the chemistry of colloids. Indeed, the most interesting lecture is that on the Antiquity of Man, where the author shows a quite exceptional knowledge of his subject. The book is really a volume of occasional essays and we would recommend the pleasure of reading them to many whose interest in chiropody is limited to their personal comfort.

OBLITERATION OF TATTOO MARKS.

A correspondent inquired in a recent issue of The Lancet as to what method could be used to remove tattoo marks on a girl's legs which were revealed by the fashionable diaphanous stockings. It is said that tattooing disappears before civilisation; but here is an unfortunate case where it has merely become more apparent. To a young woman of the period it would, of course, be supererogatory to point out the possible uses of superimposed pigments: presumably they are for some reason inapplicable or unstable in this particular case. It has been suggested that the obvious solution is to re-tattoo each mark with flesh-coloured pigment, but apart from this unattractive method, there are various other courses for which success is claimed. From Messrs. Thos. Christy and Co., of 4, Old Swan Lane, Upper Thames-street, E.C. 4, an account reaches us of the virtues of a preparation named Extaetol, which is made in Germany. The pigment is brought into contact with the remedy by application after pricking the skin with needles over the marks. The ointment removes part of the corium and the active process takes about six days; the instructions should be carefully considered before ordering. Skillem recommends in the *Philadelphia Medical Journal* (June 18th, 1898) glycerole of papain as the most efficient and least painful agent. It is pricked in over the tattoo marks after desensitisation with ethyl chloride spray. The following has also been suggested, but cannot be guaranteed. Salicylic acid which has been massed with glycerine to the consistence of dough is applied over the marks with a compress and strips of adhesive plaster and is allowed to remain in contact for some time. After the first dressing the epidermis over the marks is removed, and a fresh application of the salicylic paste applied. Usually, the second application removes the marks, but sometimes it is necessary to make a third. The treatment must be applied very cautiously.

APOPLEXY OF THE SOFT PALATE.

As long ago as 1892 Le Jeune, of Boulogne, drew attention to a condition of small hæmatomata of the soft palate which he called "apoplexie de la luette." Bosviel in 1911 recorded a similar case under the title "apoplexy of the tonsillar fold." The swellings are produced by the spontaneous rupture of small vessels and subsequently break through the mucous membrane and cause a hæmoptysis. There is little or no danger involved, but the patient may be gravely alarmed or subjected to considerable discomfort. MM. J. Garel and A. Gignoux, writing in a recent issue of the *Journal de Médecine de Lyon*, regard the condition as not uncommon, although seldom recorded. They have collected 17 cases. It may arise even during sleep, as in a case of Bosviel's, but more usually in the course of a meal, evidently as the result of contraction of the palate. The patient suddenly experiences discomfort in the throat, and if the hæmatoma be a large one the sense of stifling may be agonising and may continue for several hours. It is immediately relieved by opening the tumour with a bistoury or galvano-cautery. More often the hæmatoma is the size of a grape-stone and ruptures by itself in a few minutes, the lacerated mucosa cicatrising in a few days. The authors have not been able to determine the ætiology; trauma undoubtedly plays a part in many instances. A man who was liable to subcutaneous ecchymoses developed a large hæmatoma on the anterior pillar of the fauces while this was being lightly massaged to expel the secretions from his tonsillar crypts. There is thus an analogy with the ecchymoses produced in the vocal cords by a vocal effort. On the other hand, there are cases where no trauma can be traced, and there seems to be a certain individual tendency to the phenomenon. One of the cases, a woman aged 30, had had a palatal hæmatoma every two or three months for 12 years, usually coinciding with the menstrual period. Other cases had experienced it on several occasions. As the false hæmoptysis may continue for several hours much unnecessary alarm may be caused by this trifling accident, and it is well for the practitioner to bear in mind the possibility of its occurrence among his patients.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Oct. 6th.

ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)
Presidential Address:
Mr. A. S. Blundell Bankart: The Physiology of Muscular Action.
A discussion will follow.
Cases may be shown, either in connexion with this subject or otherwise.

Thursday, Oct. 8th.

NEUROLOGY: at the Middlesex Hospital, Berners-street, W. 1, at 8.30 P.M.
Presidential Address:
Dr. Campbell Thomson: The Work of Sir Charles Bell in Relation to Modern Neurology.
Drawings and specimens will be exhibited.

Friday, Oct. 9th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
1. Dr. Parsons-Smith: Two Cardiac Cases.
2. Dr. Douglas Firth: Bronchiectasis.
3. Dr. Bernard Myers: (*a*) Transposition of Viscera. (*b*) Morbus Cordis of Unknown Origin.
4. Dr. L. S. T. Burrell: (*a*) Clubbing of Fingers and Toes. (*b*) Abdominal Tumour.

OPHTHALMOLOGY: at 8.30 P.M. (Cases at 8 P.M.)
Discussion:
Penetrating Injuries of the Eye.
Opener:
Mr. Gray Clegg.
Other Speakers: Mr. G. H. Pooley, Mr. Harry Lee, Mr. Goulden.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Oct. 5th, to Saturday, Oct. 10th.—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C. Special course in Laryngology, Rhinology, and Otology. Clinical Course and Operative Surgery Course, of which one or both may be taken. Operative Surgery Class daily 9.30 to 11.30. Clinical Course most days, 9–5. In- and Out-patient Operations, Clinics, and Lectures.—London School of Hygiene and Tropical Medicine, Endsleigh-gardens, N.W. First two of a series of eight clinical demonstrations. Tuesday and Thursday, at 2, by Dr. G. C. Low and Dr. Manson-Bahr. The subjects considered will be the more important diseases of tropical countries, illustrated, if possible, by cases.—Royal Free Hospital, Gray's Inn-road, W.C. Lecture-demonstration on Treatment by Electro-Therapy on Wednesday, Oct. 7th, at 5.30, by Dr. C. B. Heald.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: October-November, 1925.

Clinical Lectures and Demonstrations.

Monday, Oct. 5th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Paraplegia and its Treatment: Dr. Riddoch.
Tuesday, Oct. 6th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Epilepsy: Dr. Adie.
Thursday, Oct. 8th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Progressive Muscular Atrophy: Dr. Martin.
Friday, Oct. 9th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Pituitary Tumours: Mr. Sargent.
The Fee for the Course, including Pathology lectures, is £5 5*s*. For those who hold Perpetual Tickets the fee is £3 3*s*.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Thursday, Oct. 8th.—12 noon, Neuronal Degeneration: Dr. J. G. Greenfield.

Course of Lectures and Demonstrations on the Anatomy and Physiology of the Nervous System.

Monday, Oct. 5th.—12 noon, (*a*) The Significance and Evolution of the Nervous System. (*b*) Methods of Investigation: Dr. J. L. Birley.
Dr. H. J. Macbride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 A.M. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2*s*.
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 o'clock, or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.
Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.
J. G. Greenfield, Dean of Medical School.

UNIVERSITY COLLEGE, London.
Wednesday, Oct. 7th.—5.30 P.M., Prof Fritz Weigert (Leipzig): The Photochemistry of Vision (public lecture in English). 7 P.M., Mr. A. H. Barker: Public Lecture on the Heating Equipment of a Large Hospital.

ST. JOHN'S HOSPITAL, Leicester-square, W.C.
Tuesday, Oct. 6th.—5 P.M., Dr. S. E. Dore: Physiology of the Skin.
Thursday.—5 P.M., Dr. J. M. H. MacLeod: Anatomy of the Skin.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
Tuesday, Oct. 6th.—4.15 P.M., Dr. F. E. Tylecote: Prognosis and Treatment of Bronchitis.
Friday.—4.15 P.M., Dr. E. M. Brockbank: Pre-Existing Disease as a Cause of Disablement in Workers.

An Address
ON
UNUNITED FRACTURES.

Delivered at St. Bartholomew's Hospital, London,

By ERNEST W. HEY GROVES, M.S. Lond.,
F.R.C.S. Eng.,
PROFESSOR OF SURGERY, BRISTOL UNIVERSITY.

When I was a student in these revered and ancient walls the subject of fractures received very scant attention in our surgical curriculum. Of course, necessity sometimes compelled the admission of a case of fracture of the leg bones into the wards, and then splints were duly applied and after some weeks the patient was sent out; what became of him we never inquired—he did not interest us. The smartness of a house surgeon was recognised by this among other tests—that he should avoid taking in fracture cases and, having taken them in, should hide the fact and get rid of the offending case as soon as possible. I remember Mr. Lockwood advising us if we ever got a fracture case in private practice to pass it on to our rival across the street, so that it might be his undoing and not ours, but beyond this, I cannot recollect any member of the surgical staff ever taking any notice of a fracture during my dressership. No doubt this is all changed now, and in the full illumination of the X rays the diagnosis and treatment of fractures are taught as embodying the most important principles of the science and art of surgery.

Causes of Non-Union.

The study of a case of a fracture which has failed to unite is one which may well absorb the interest of the pathologist and the physician as well of the surgeon and the mechanic. Why does repair sometimes fail? What determines the ordered balance between tissue formation and tissue absorption? What is the difference between an osteoblast and an osteoclast? What is the vital relation between the cells and the intercellular material of the skeleton? Such are some of the questions which are suggested and which I find easier to ask than to answer.

Let us consider the last question a little more closely, for it affords a good illustration of the baffling nature of the problem of bone pathology, and it is very intimately connected with explaining the nature and determining the treatment of an ununited fracture. All connective tissue and especially bone and cartilage are distinguished by the large proportion which the intercellular material bears to the cellular element. Is this intercellular material living or dead? A piece of bone is regarded as dead if it contains neither blood-vessels nor cells. But according to this definition all the extra cellular material of the bone is then dead; it is a secretion or excretion of the living cells which can be laid down or taken up according to the necessities of the moment.

The endoskeleton of the vertebrate, like the exoskeleton of the invertebrate, is formed by the living tissues, but is outside them. Any piece of human bone may become temporarily deprived of its blood-supply and its cells all die, and yet in a very short time new blood-vessels and new cells invade the dead bone and the dry bone truly lives once again. On the other hand, a devitalised portion of bone may remain for an indefinite time without blood and without cells, an indolent mass incapable of growth or repair. This, in fact, is the condition of the ends of the bones in many cases of ununited fracture.

The causes of non-union may be grouped as follows:—

Mechanical—
- Gap between the bone ends.
- Unrestricted mobility.
- Interposition of soft parts.
- Foreign bodies.

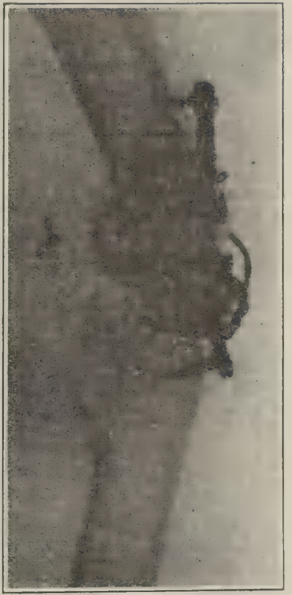
Vascular—
- Sepsis, destroying the vital elements.
- Sclerosis, the bone canals are closed and the cells imprisoned.
- Atrophy, the vital elements disappear and only an earthy shell remains.
- Fibrous tissue and cartilage cover over the bone ends and so imprison the vital elements.

Disease—
- Infection, pyogenic or specific, tubercle, gumma.
- New growth—
  - Fibrocystic disease, myeloma.
  - Sarcoma, carcinoma.

Space does not permit of the discussion of each of these causes, and I must be content to emphasise one or two points.

It often happens that several of these causes coöperate. Thus, in the fracture of the neck of the femur, it is difficult to fix the bones, and with the ordinary splinting there occurs mobility, associated with want of apposition and the interposition of part of the capsule of the joint. The proximal fragment has a very poor blood-supply and atrophy quickly takes place. Again in the case of the shaft of the humerus, the difficulty of efficient fixation is the prime cause of the frequent non-union. The bone ends throw out granular tissue or pro-callus, but constant movement prevents this bridging the gap. In the meantime muscle and fascia wrap closely round the bone ends, and each becomes clothed in fibrous tissue or fibro-cartilage. The importance of mobility as a cause of non-union has been obscured by the teaching of those who advocate early movement of a limb as conducing to rapid restoration of function. But there is no real conflict of opinion. Movement of the limb as a whole and of the muscles covering the fracture is good because it promotes vascularity. But movements of the bone ends against one another in the early period after a fracture certainly prevent union.

Fig. 1.



Ununited fracture of humerus, treated by plate, wires, and screws two years previously. (For result of grafting operation, see Figs. 4 and 5.)

One cause of non-union which is not uncommon is the inefficient application of screws and plates or wire in the treatment of a fracture. This, too, has been the subject of much misapprehension. It is commonly said that it is the malign influence of the foreign body which has hindered the vital repair. But this is not the case. Bones tolerate foreign bodies very kindly, provided they are fixed and give fixation. But it is the small plate which soon works loose, or the badly applied wire which works the mischief, causing friction, destruction of granular tissue, and non-union. It is easy to provide abundant proof of this both from experimental and clinical evidence. Fig. 1 is a good illustration of mechanical fixation which provides the maximum of frictional irritation with the minimum of mechanical rigidity. That there was nothing at fault with the bone itself is proved by the kindly way it healed after a bone graft (see Figs. 4 and 5).

VARIETIES OF NON-UNION.

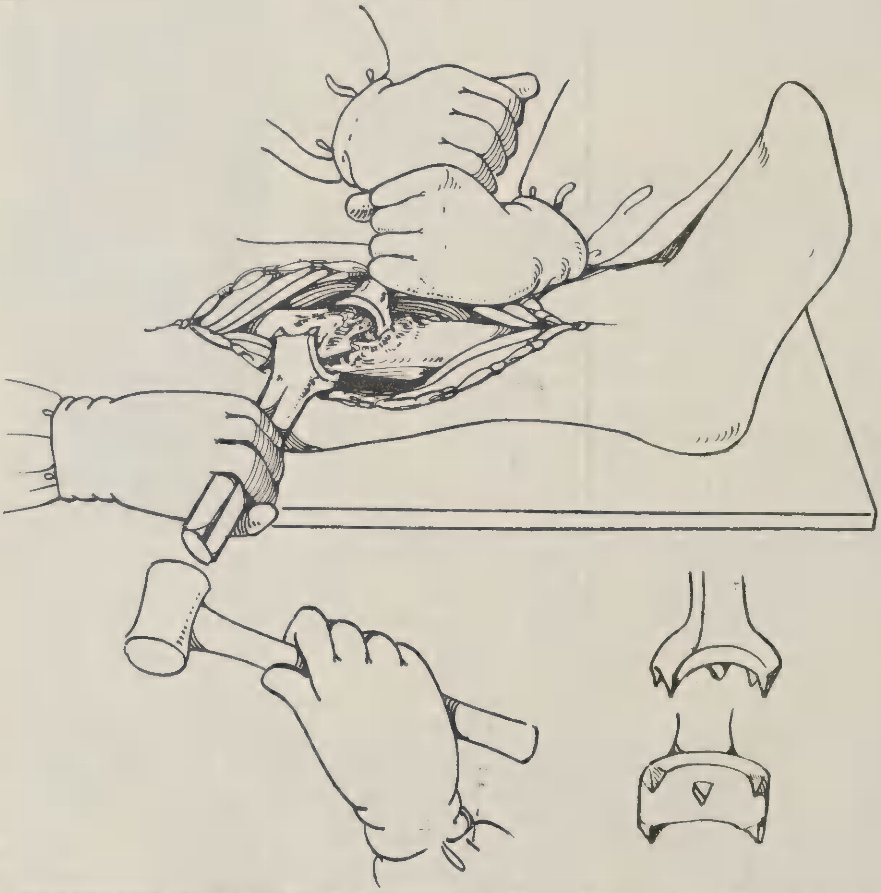
There are at least four different varieties of ununited fractures, and each variety has its own structural peculiarity and requires special treatment. They are :—

(*a*) *Delayed Union*—
Mere cellular inactivity.
No callus and little or no fibrous tissue.

(*b*) *Non-union*—
1. Fibrous union : Fibrous tissue or fibro-cartilage between and connecting the bone ends.
2. Pseudarthrosis : Bone ends eburnated and covered with fibro-cartilage. A joint cavity with capsule and synovial fluid between the ends of the bones.
3. Gap fracture : A piece of bone lost, the bone ends held apart by the companion bone. The bone is usually thin and atrophic.

It is not always possible to distinguish between the first and the second varieties—i.e., between delayed union and fibrous union, but the other two varieties—the false joint, with its flail-like mobility, and the gap fracture—are quite distinct. In merely delayed union the bone's ends are in contact, but callus does not form in such a way as to unite them. Such callus as there is is only the internal callus which seals up each marrow cavity. The X rays show no change in the bone except for a slight blurring of the distinction between the cortical and medullary layers. It is a state of cellular indolence and inactivity, which can generally be quickened into healthy vital repair by an appropriate stimulus. In fibrous union, on the other hand, the bone ends are thickened, eburnated, and greatly increased in density as seen by the X rays. The bone ends are covered in fibrous tissue or fibro-cartilage, whilst blood-vessels and osteoblasts alike are strangled or imprisoned in hard sclerotic bone. In making this distinction, however, it has to be borne in mind that the one condition leads to the other, and it is therefore not always possible to draw a sharp line of demarcation between them. From a practical point of view, delayed union is a condition which can be cured by non-operative or simple comminution methods, whilst true fibrous union will require open exposure with resection of the eburnated bone ends.

FIG. 2.



Fractured tibia exposed and treated by subperiosteal comminution ; inset shows jaws of instruments used.

NON-OPERATIVE METHODS OF TREATMENT.

In all doubtful cases when not more than six months have elapsed since the fracture, it is worth while to give a good trial for a period of about three months to non-operative methods. Such a case is often presented by a fracture of the lower third of the tibia. Perhaps six months has passed since the accident, the broken bone presents distinct mobility but not much pain, and the X rays show no change in the bone ends except a little rounding off of the sharp contour. It is easy to make a mistake in such a case by treating it as if it were a recent fracture and putting on a plate. It may be true that if the fracture had been plated in the first place union would not have been delayed. But the essential fact of delayed union—viz., the cellular inactivity of the vital elements of the bone—now dominates the situation, and mere plating is more likely to make matters worse than better. To apply a plate requires that the bone ends should be partly stripped of their vascular covering and bored with holes, but then the bare area and the fresh holes are covered or plugged with plate and screws, a process which does much to hinder and nothing to promote callus formation.

There are three non-operative methods available and these may be used singly or in combination. They are : (1) voluntary movements, the fracture being protected with a splint ; (2) passive congestion with massage ; (3) injection of blood or blood products in and around the fracture.

In the encouragement of active movements the limb must be so protected by a case-splint that absolute rigidity without lateral movement is afforded to the bone, whilst the joints above and below are left free. The contraction of the muscles promotes hyperæmia and also pulls the bones together. In the case of the tibia the patient is made to walk, and this is a most efficient means of forcing the bone ends together and so promoting a frictional stimulus to callus formation. This type of treatment is very practical because it will enable most patients to resume their active work instead of keeping them in prolonged invalidity. The second non-operative method is the "damming and hammering" advocated by Owen Thomas. A piece of rubber tubing is placed round the limb above and below the fracture as tightly as can be borne without altering the arterial pulse and so kept for several hours daily. With this is associated a heavy percussion massage of the limb aimed at promoting tissue stimulation.

The injection of blood or of serum or fibrin has not been used much in this country, and its value is suggested chiefly by experimental evidence. It is really more difficult and nearly as painful as the open exposure of the fracture, and therefore to me it hardly seems worth while. Animal experiments are misleading in this matter. It may be true that blood injection round an injured bone will intensify callus production; but that is when the bone injury is recent and the bone healthy—there are plenty of bone cells and nothing to imprison them. But in an old fracture matters are different. The bone cells are locked up in a hard dense bone, the surface of which is sealed, and blood bathing the outside of such bone has very feeble power to liberate its essential and vital elements.

OPERATIVE TREATMENT.

Whenever union has been delayed for more than 12 months or when there is increasing mobility between the fragments associated with an X ray picture of rounded bone ends separated by a definite gap, then an open operation will be necessary if cure is to be effected. The actual nature of the operation will depend upon various circumstances, and it is a matter for skilled judgment founded upon experience.

The following are the principal considerations which must be taken into account before deciding upon an operation and in choosing the operative method: Age, health, and temperament of the patient; amount of disability, with and without a suitable splint; sepsis; existence of other lesions particularly those of joints, nerves, or blood-vessels; deformity; relation of the bone ends to one another—i.e., contact, overlapping, or gap; conditions of the bone ends, sclerosis, or atrophy.

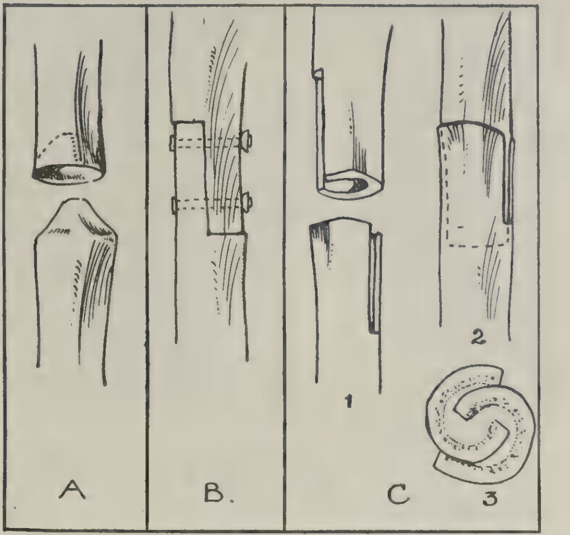
It must be borne in mind that the operation may be one of great difficulty or even danger, and that it makes a great demand upon the patient's vitality and powers of repair. It requires a patient who is keen, healthy, and young, in temperament if not in years. In some cases the amount of disability is very little. For many years Dr. Livingstone continued his active work as an explorer with an ununited fracture of the humerus, and I have known a busy general practitioner continue his work suffering from the same injury. Sepsis, whether actual or remote, is always a serious hindrance to reconstructive operations, although it may not prevent the adoption of the simpler revitalising procedures. The existence of serious complicating lesions of the joints, blood-vessels, or nerves may make it wiser to choose amputation rather than reconstruction, and this applies more particularly to fractures of the tibia.

Deformities should be corrected as far as possible before the fracture is dealt with, so that the freshly united bone is not subjected to any undue strain. The relation of the bone ends to one another should be carefully considered before deciding what type of operation is to be done. It is much better to aim at bringing the bone ends into contact and wide contact with one another, even at the sacrifice of length, rather than to depend upon bridging a defect with a graft. If there is much overlapping of the bone ends it is seldom possible or desirable to restore the bone to full length by traction—it is better to unite them side by side in a step-cut operation. If the bone ends are greatly sclerosed or much atrophied, they will repair slowly, and the mere addition of a graft will not supply the lost elements of vitality. The essential for success is the wide contact of healthy vascular bone surfaces, and if it is necessary to use a graft then this must have wide contact with healthy vascular bone at each end.

STIMULATION OF THE BONE ENDS.

Whatever may have been the first cause of non-union the ultimate conditions which make it permanent are want of contact and failure in vitality of the bone ends. If, then, the bone ends can be brought into wide contact without strain or deformity, it is only necessary to arouse their dormant vitality and union will take place. In the first place, all the dense fibrous tissue between the bones is removed, and raw surfaces of bone secured by scraping and chiselling. But such surfaces are usually indolent, bloodless, and sclerosed. They must be broken up so as to open up fresh blood channels and liberate the bone cells. Multiple drill holes or saw cuts may be made into the bones, or they may be chiselled into fragments. The latter is certainly most effective, because it is more drastic than drilling or sawing and it does not choke the fresh surfaces with the bone dust caused by drill or saw. But it is liable to split fragments clean off the bone, and such fragments will be very inert in the matter of repair. Recently I have adopted a modification of the chiselling method which is a sort of hammer and anvil procedure and aims at *subperiosteal comminution* (Fig. 2). The bone ends are exposed but the thickened periosteum over them is left undisturbed. The fibrous tissue between the bone ends is cut away by chisel and spoon. Then each bone end in turn is taken between the jaws of two spiked steel instruments, which are curved to fit the convexity of the shaft. These are then hammered together, using a heavy hammer, so as to crush the bone and periosteum, but not separating one from the other. Free oozing will, of course, result from this, and the two comminuted bone ends are left in the midst of a hæmatoma over which the soft parts are carefully sewn in several distinct layers without drainage. The limb is put up in a case-splint and active exercise taken as soon as possible.

FIG. 3.



Fitting methods: (A) Double cone. (B) Step-cut. (C) Sectoral interlocking: (1) Ends cut, (2) interlocked, (3) in section.

I would advocate such treatment for those cases in which union is merely delayed without gross change in the bone ends. It is simple and free from any risk except that of failure. If it fails it does not prejudice the success of a grafting operation done later.

SHAPING AND FITTING OPERATIONS.

But in all cases of definite non-union, the bone ends are so unhealthy that they must be not only cut into but cut away so as to secure a wide contact of raw surfaces of fresh bone. And this should be done in such a way as to fit and fix the ends together. Four things are necessary: Fresh bone—i.e., provided with blood-vessels and osteoblasts, wide contact, close apposition, and firm fixation. Whether it is that the osteoblast will not venture out to any distance from its bony origin, or whether an osteoblast ceases to lay down bone when it is at a distance from its parent bone, is not known, but the fact is undoubted that new bone is very rarely formed except in the close neighbourhood of existing bone. Therefore if fresh bones are fitted and fixed firmly together they will unite into one solid bone, whereas if they are in loose apposition they will only become tied together by fibrous union.

FIG. 4.

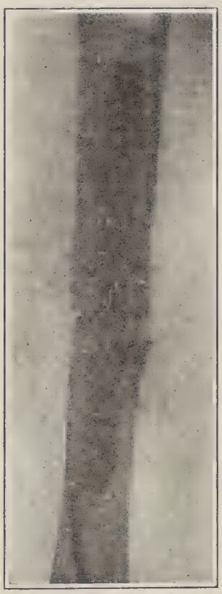


FIG. 5.

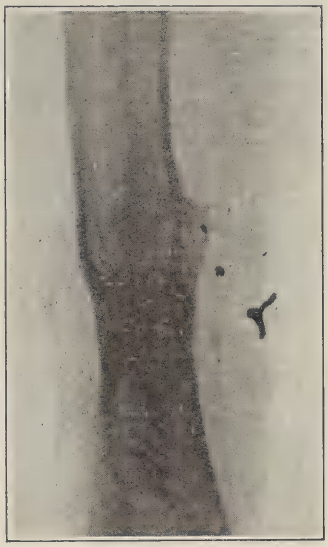

FIG. 4.—Fractured humerus (same case as Fig. 1) treated by autogenous intramedullary graft fixed by "split-and-thrust" method. One month after operation.
FIG. 5.—Same case as Fig. 4. Two years later.

FIG. 6.

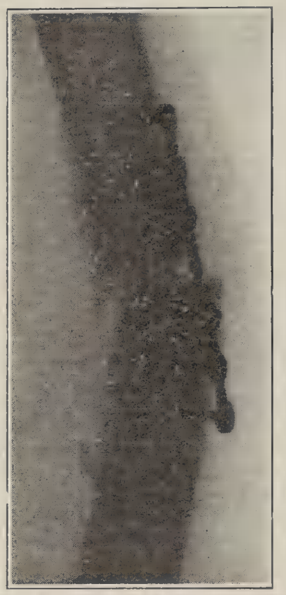

FIG. 8.

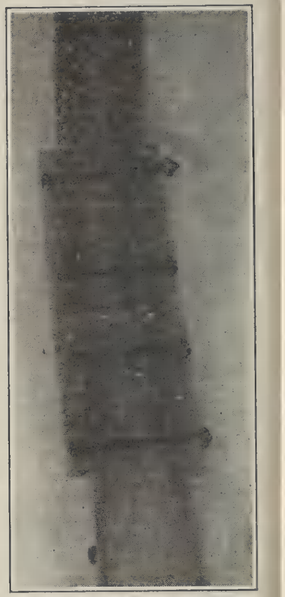

FIG. 6.—Ununited fracture of femur treated 12 months previously by inadequate plating.
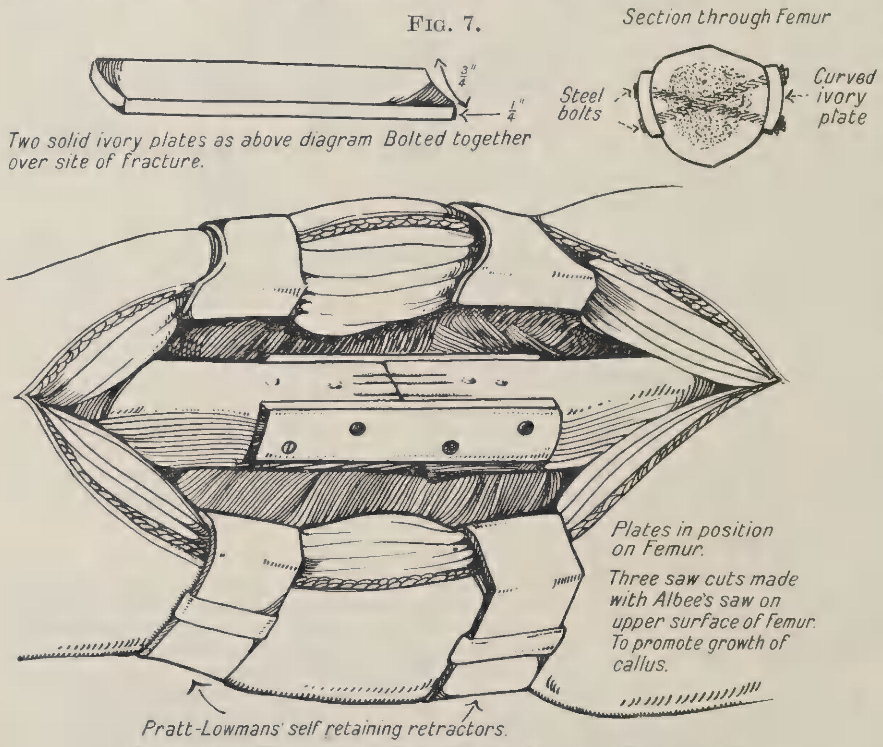
FIG. 8.—Same case as Fig. 6. After operation, by a pair of ivory plates, bolted together.

A good illustration may be given from the joinery of a cabinet maker or carpenter. In such work all joining is done by accurate fitting. If glue is used, it is only to fix accurately apposed surfaces and not fill up cracks or deficiencies. No more should be asked of the reparative callus than a carpenter asks of his glue—i.e., to knit together surfaces which truly fit and are firmly fixed.

FIG. 7.



3/4"
1/4"
Two solid ivory plates as above diagram Bolted together over site of fracture.
Section through Femur
Steel bolts
Curved ivory plate
Plates in position on Femur.
Three saw cuts made with Albee's saw on upper surface of Femur. To promote growth of callus.
Pratt-Lowmans' self retaining retractors.

Same case as Fig. 6. Operation by bolting on pair of ivory plates.

The actual shaping of the bones after sclerotic tissue has been cut away should be adapted to the condition of the bones, the shape of the fracture, and the advisability of shortening the bone. Thus transverse fractures may be shaped as a double cone and fixed by a peg or a plate (Fig. 3, A). Oblique fractures may be step-cut so as to give a wide overlapping and fixed by bolts or bands (Fig. 3, B). Or an atrophic bone may have a piece taken out of its circumference and then be made to interlock with its fellow by engaging one edge of each bone in the marrow cavity of the other, a device which may be described as sectoral interlocking (Fig. 3, C).

It will be noted that all these reconstructive operations involve the shortening of the bone. This is of no great importance in the humerus. In the femur it is better to have a short strong leg than an ununited fracture. It is wise not to attempt full elongation of the thigh bone. It may be given one week's traction by a 25 lb. weight applied by a transfixion pin, and then at the operation the bone should be joined with some overlapping. It is dangerous on account of shock to pull the leg out to its full length, and it is fatal to the fixation if it be put up under strong tension. In the forearm and lower leg the fitting operations usually involve an osteotomy of the companion bone. Having fitted the ends together they certainly should be fixed. Such fixation may be by metal bolts, ivory screws, bands, or wire, or in many cases tendon ligatures, silkworm gut, or stout silk will suffice. If metal fixation can be dispensed with, so much the better, but it is absurd to make the non-use of metal sutures a guiding maxim of bone surgery. Having fixed the fitted bones together by proper sutures the limb is immobilised by an external splint or plaster-of-Paris.

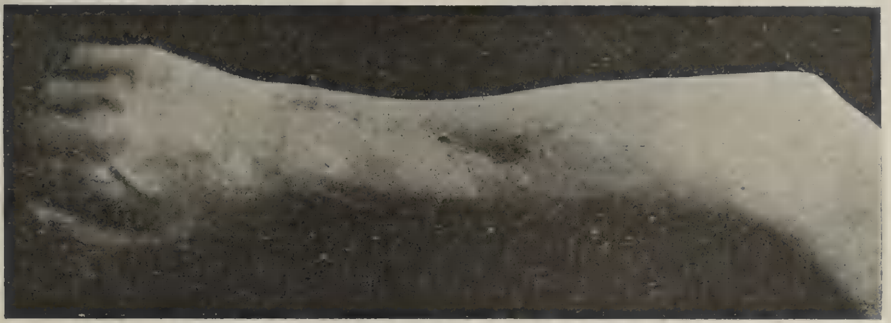
To recapitulate the essential points. Secure fresh bone by cutting away the unhealthy ends; provide wide contact of the fresh bone surfaces by accurate fitting; ensure close contact by proper sutures of which the metal bands and bolts are the most reliable; and get proper prolonged fixation by an external splint which must be worn for three months at least.

BONE-GRAFTING OPERATIONS.

The ideal and obvious method of treating ununited fractures is by putting in a bone graft. But it is well at the outset to realise that this method has very definite limitations, and that the conditions for success are very exact.

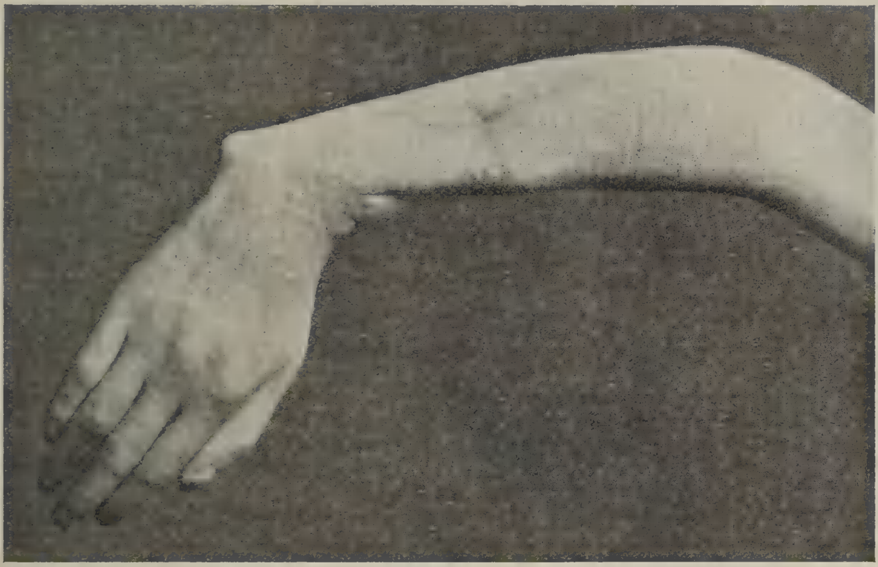
A piece of bone cut from the living bone of the patient is endowed with very limited vitality. It has living bone-cells, but for the most part these are locked up in the depth of the dense skeletal tissue. It has blood channels cut off from the active circulation, and it has a strong rigid frame which can be used as an internal splint or strut, whilst this framework is porous and is thus capable of acting as a scaffold work into which new bone tissue may penetrate from neighbouring active bone. It has no power of independent growth, and if it is placed in any living tissue other than the skeleton it rapidly withers away. Its power of producing new bone is very limited, and by many authorities is considered non-existent. When used to repair a defect in a long bone it can act in four ways. First, as an internal fixation splint; second, as a strut by which continuity being restored to a broken bone, the latter is provided with a functional stimulus; third, as a scaffold, in and around which new bone is built up; and fourth, as a source of new bone. The functions of the graft as an agent of fixation and osteo-conduction are clear and obvious, whilst that of osteogenesis is problematical. But a piece of dead bone will carry out the function of fixation and conduction, and it often becomes a question whether it is worth while using living bone just for the sake of its osteogenetic power. If a gap has to be bridged, then living bone must be used for the graft, but if the pieces of the broken bone can be brought into contact and the graft buried in living bone, then dead bone may be used, and should be used, if greater strength is demanded than can be provided by a live graft.

FIG. 10.



Same case as Fig. 9 after transplanting ulna into radius.

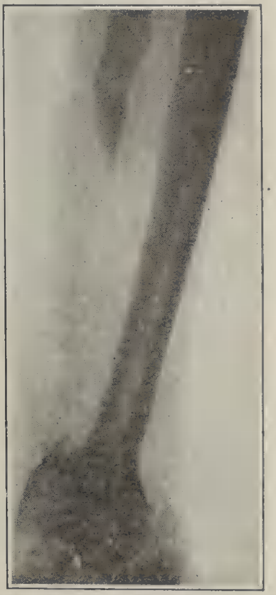
FIG. 9.



Gap fracture of radius resulting from gunshot injury in which bone grafting had twice failed.

Exactly the same principles apply to the fitting and fixing of a graft as have been laid down for the fitting and fixing of the bone ends of an ununited fracture. That is to say, wide contact with live bone, firm fixation, and efficient immobilisation. And if the graft is used to bridge a gap it must be as stout and as strong as the bone it has to replace.

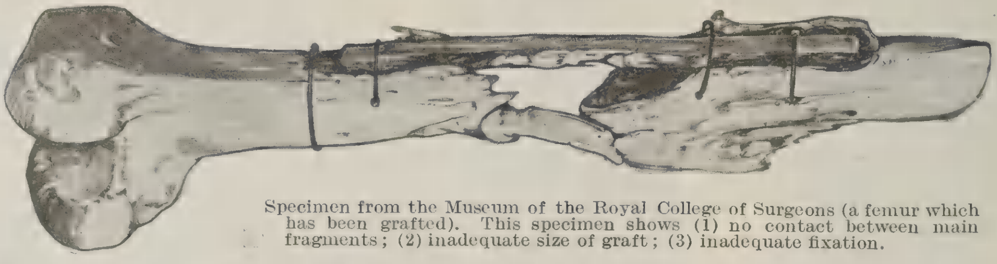
FIG. 11.



Same case as Figs. 9 and 10. X rays three years later. Strong working hand.

An autogenous graft is usually cut from the inner surface and crest of the tibia, which in an adult is capable of providing a piece of bone 8 in. long, $\frac{3}{4}$ in. wide, and $\frac{1}{2}$ in. thick. A motor-driven circular saw cuts the graft quickly, neatly, and with precision, and I have seen no evidence that the use of this instrument produces any interference with the vitality of the graft. It is not essential to take periosteum with the graft, although I think it is an advantage, because the attached membrane will help as a medium of vascular exchange between the graft and the tissues of the bed into which it is laid.

FIG. 12.

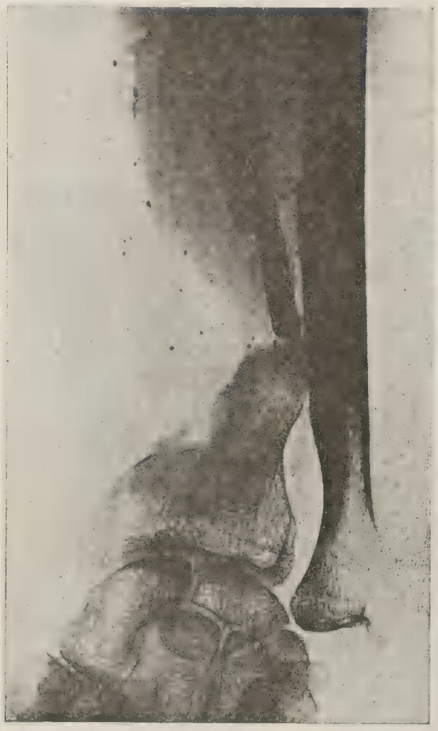


Specimen from the Museum of the Royal College of Surgeons (a femur which has been grafted). This specimen shows (1) no contact between main fragments; (2) inadequate size of graft; (3) inadequate fixation.

The fitting of the graft into the broken bone may be carried out in various ways, driving it into the marrow cavity, embedding it in the surface, or by combining these methods, placing one end in the medullary canal, and fixing the other in a slot cut in the cortex.

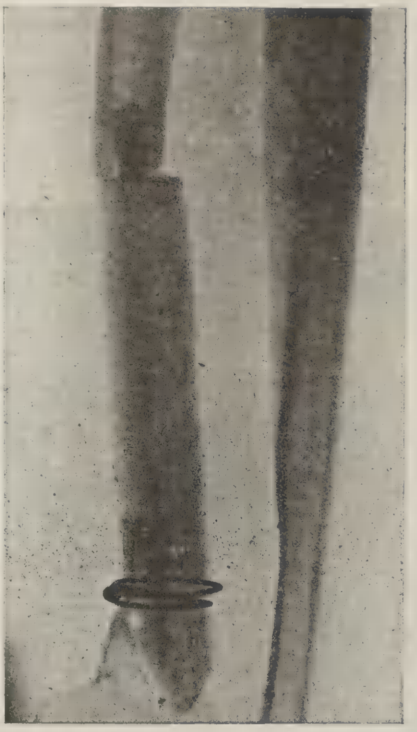
Intramedullary Grafting.—If a bone graft of suitable size and shape be driven into the marrow cavity of a tubular bone it will rapidly become consolidated with the latter. I think this admits of no doubt, and yet intramedullary grafting has fallen into undeserved disrepute because of the technical difficulty of placing the graft tightly in each fragment. This can be accomplished in various ways. The graft can be driven through the end of the bone so as to nail one fragment to the other. This is possible for a fracture near either extremity of the humerus or for one at the proximal end of the femur or ulna. Or it may be driven into one fragment, whilst the other fragment is split to receive it and then tied together with wire or silk (Figs. 4 and 5). In dealing with a gap fracture, the graft is shaped like a cricket bail, one end being driven into one fragment whilst the other is manœuvred into position by angulating the other fragment out of the wound and slowly straightening the bone whilst the graft is engaged in its cavity. Or the graft may be made in two pieces, one is driven into the marrow cavity of each fragment, and the two grafts are then fixed together. Of these various devices the thrust-and-split method is the most satisfactory, because it gives the greatest contact between the graft and the host bone.

FIG. 13.



Fractured radius resulting from gunshot injury. Shows graft too small, no contact, and no fixation.

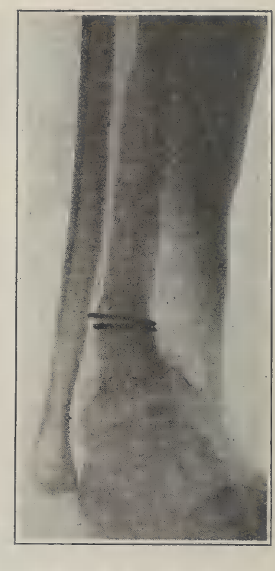
FIG. 14.



Same case as Fig. 13 with graft of adequate size and fixation.

Cortical Inlay Grafting.—In this method a slot is cut in the surface of both fragments of the fracture, and into this slot is fixed a graft which is made to fit accurately into the slot. The actual fitting is facilitated by using an aluminium plate as a template to measure the size both of the slot and the graft. It necessitates a very free exposure of the broken bone, because at least one-third of its length should be involved in the grafting operation in order to give strength and rigidity. It is particularly suited for the tibia or one of the forearm bones, because it supports one side whilst the other side is held by the companion bone. The graft is fixed in its bed by accurate fitting, by sewing the soft parts over it, or by bone nails or screws.

FIG. 15.



Same case as Figs. 13 and 14. Two years later.

Use of Beef Bone or Ivory Pegs or Plates.—If the graft has to be buried in living bone then a strong dead graft is often better than a weak living one

Thus, in a fracture of the neck of the femur an ivory or bone peg used as a nail driven in through the great trochanter will give a good result, provided that accurate apposition of the fractured surfaces without interposition of soft parts be secured. In an ununited fracture of the femur, where it is desirable not to shorten the leg by a step-cut operation, it is difficult to get a living bone graft strong enough for the purpose. In this case a pair of ivory plates (Figs. 6, 7, and 8) may be used or else a tibial bone graft may be placed on one side of the fracture and an ivory plate on the other and the two plates then bolted together.

Supplementary Bone-grafting Methods of Doubtful Value.

There are certain methods of bone grafting, founded chiefly on theoretical considerations, which must be considered briefly. These are the use of so-called wafer grafts formed of periosteum with a thin layer of underlying bone, and the employment of bone chips. In my own practice and in experimental work both these methods have invariably led to failure. I would therefore relegate them to a very subsidiary rôle in the treatment of ununited fractures. It is possible, when the fracture has been fixed by one of the above-mentioned methods, that by wrapping a piece of periosteum with adherent chips round the fracture, or by packing in little bits of bone taken from the crest of the ilium the consolidation may be hastened, but I am not clear even on this point. Certainly the process of absorption is much more evident than that of callus formation.

Bone Shortening or Bone Substitution.—It not infrequently happens that more than one operation has failed to cure an ununited fracture. If this is the case with the forearm or the leg, there is another alternative to abandoning the case or submitting it to a case-splint or to amputation. This consists in shortening the companion bone, or substituting one bone for the other. In a gap fracture of the tibia a piece may be taken out of the fibula, sufficient to allow of the tibial fragments being made to impact or overlap. In a gap fracture of the radius, in which grafting has failed, the ulna may be divided and the proximal portion implanted into the distal part of the radius (Figs. 9, 10, 11). This gives a strong, straight arm, curing the radial deviation of the hand, although not permitting movements of pronation or supination.

Causes of Failure.

Apart from certain conditions—e.g., sepsis, active or latent, or the presence of general disease or debility which prevents the success of any surgical procedure—the local cause of failure of operations done for ununited fractures may be grouped together under the following heads: 1. Inadequate contact of bone ends (Fig. 12). This may be due to the sclerosed bone or fibrous tissue not having been cut away or to the raw surfaces not having been fixed together efficiently. 2. Inadequate fixation of the fracture either by reconstructive operation, graft, or splint. 3. Inadequate grafting in respect of the graft being too small, having no contact, or not being fixed to the host bone (Figs. 13, 14, 15). 4. Inadequate splinting of the limb after operation. 5. Excessive tension. If great force is used in reducing an old fracture there is immediate danger of shock, and later, risk almost amounting to certainty, of the mended fracture being pulled apart by the tension to which it is subjected.

The successful treatment of an ununited fracture will often test your skill as a mechanic, your technique as a surgeon, and your patience and optimism as a mender of the maimed; but the results of success are well worth striving for, because they are nothing less than converting a cripple into a whole man, and if in accumulating the experience upon which this lecture is founded I have made many mistakes and encountered many failures, my sincere hope is that you may avoid the mistakes and be rewarded by unvarying success.

An Address

ON

AVENUES IN MEDICINE.

Delivered at the Opening of the Winter Session of the London (Royal Free Hospital) School of Medicine for Women

By Sir CHARLES SHERRINGTON, O.M., G.B.E., M.D. CAMB.,

PRESIDENT OF THE ROYAL SOCIETY.

ON the opening day of the session, with some here for whom it is the commencing of a profession, our thoughts turn naturally to questions of what that profession has to offer and what it demands. The perspective of the avenue along which the profession of medicine is reached has many interesting points as viewed from either end, though I can deal with but a few among them.

Here in this school I imagine all students enter the profession for no other reason than that medicine earnestly attracts them. That pledge of enthusiasm is a valuable asset for the student herself and for her teachers, as also for the school and for the profession. If we ask what ground there is for that enthusiasm, we may in the first place as practical people take this, that there are in the nature of things not so many callings open to women as to men, and that medicine can and does provide for women to-day a means of earning an independent living. The average annual earning of the medical practitioner in this country to-day is, I believe, put at between £500 and £600 a year. I see little to suppose that that estimate is not applicable to the woman as well as to the man practitioner. It is not, to my mind, a discouraging average in the era before us, which must perforce be one of national economy and fortitude.

It is an average which doubtless regards chiefly the general practitioner. Though general practice is the main path of the profession, there are other far from negligible though relatively exceptional ones. There is consulting work and there is specialist work. Some of those present here to-day brilliantly exemplify the success in these that is attained by women. There are also medical branches of Government service, and I need not name to you women, and from this school, who hold distinguished and responsible positions in those services. Dame Janet Campbell, a senior medical officer of the Ministry of Health, we remember, is a former student of this school. And there are, further, other public services as well, municipal and county posts. Perusal of the list of registered medical women, former students of this school, show how considerable a number of such posts are occupied by them.

But no more than does it satisfy man shall it satisfy woman to live by bread alone. Bread alone will not account for enthusiasm in the choice of medicine as a calling. Medicine has been termed with some justice a poor trade; but at the same time it is known as a noble profession. If we can justify this latter belief it is a truer source for enthusiasm. And it is a claim that can be justified on many grounds.

Medicine a Progressive Science.

One of these grounds, though I do not say the main one, is yet a memorable one, and rises early to my mind. Medicine is not only an honourable art but a progressive science. In this respect it is an exceptional calling; indeed, among callings available for women it stands in this respect almost alone. Like it engineering is at once a science and an art; but engineering is not a profession available for women.

Those two professions, medicine and engineering, typify in the work-a-day world and for the thoughtful historian what the modern growth of science is doing in the modern world. It is to underrate their significance in modern life to suppose that these influences are increasingly changing merely the outer features of our surroundings. They are changing and developing the inner features also—the mental outlook and the range of life. And if to engineering science be due those of these changes which most catch the eye, to the advance of medicine are due developments as far-reaching and beneficent, and, to the initiated even more than to the uninitiated, fraught with meaning for human welfare, and are a source for enthusiasm. The swift forward moving of medical science in this present may assuredly stand to the future historian as the outstanding mark of the progress of civilisation in our era. A woman who has yearning to enter to the uttermost into some strong current of the abiding progress of the time we live in, and to feel and understand it, and to play a rôle in it, can rest assured that to enter medicine will give her opportunity for that, and in the fullest and most beneficent of ways.

At risk of repeating before an audience already well aware of them things that are commonplace knowledge even outside the profession, may I instance the speed of medical advance by mentioning a few outstanding points which medicine has attained within less than living memory.

Take the diseases distinguishable as infective. To know them as such is the beginning for the control of them. Tuberculosis and malaria, those two scourges of mankind, have in the last 45 years been opened to such control. A further key to mastery over infectious disease is to get disentangled hold of the particular infective agent. The last 40 years have seen that done for diphtheria, glanders, cholera, tetanus, Mediterranean fever, yellow fever, plague, dysentery, and syphilis. Through the long ages of its previous history medicine had travelled without in one single instance achieving such a step. Hippocrates, father of medicine, had he done so would have been reputed a god; more important, he would have changed the course of human history.

On the heel of such specific discoveries have followed the modern knowledge and employment of immunity, proving, if further proof were needed, the rightness of Jenner's vaccination against small-pox, by elucidating the principle on which it rests. Pasteur began to vaccinate—he called it so, in tribute to Jenner—against bacterial disease by inoculating with the specific bacteria attenuated. What lessening of human and animal suffering date from and because of that step of only 42 years since. In recent eloquent witness stand the statistics of control over typhoid obtained for the armies in France by vaccines introduced by Sir Almroth Wright and extended by Sir William Leishman. Then there is the whole relatively new subject of serology, potent for prevention, for remedy, and for diagnosis. Diphtheria has been largely robbed of its terrors, though Roux and Yersin's work on the diphtheria toxins dates to not 30 years back.

And the progress goes forward, with change, but no sign of halting. Thus, the intriguing bacteriophage, which seems a germicidal subgerm. Again, the new step of knowledge in regard to cancer, stressing the interaction of essential causal factors, and the yet unexhausted power of the microscope for discovery. The invisible viruses are beginning to be made visible.

And, infectious diseases apart, progress of the past five years has turned the position in regard to rickets. The enemy forces have been located. They are recognised as two—deficiency from diet of an elusive substance traceable to the plant world which is based on sunlight, and deficiency of sunlight itself. An era has begun when child-life can be saved from a crippling disability. And in this victorious campaign women have borne a conspicuously important and distinguished share. Then, again, the discovery of insulin came but three years ago, and it is now alleviating cases of suffering the civilised world over. Such instances, taken almost at random, surely justify enthusiasm.

It is difficult for the student or the medical curriculum to find time for all the student has to learn. Introductory science has perforce to be curtailed because it is introductory. Economy of time can be obtained by getting as much as possible of the introductory science done in ordinary school years before coming to the medical school. This is the more advisable because these scientific subjects are to-day essential to general education. We all know the disabilities, conversational and for citizenship, which adhere to otherwise educated people by reason of lack of school instruction in such science as should be part of common knowledge. But wherever and whenever the adjunct sciences are taught with a special view to medicine, it should not be forgotten that for application of them to medicine it is the principles not less than the ad hoc facts which are required. The former rather than the latter enable the student when she or he leaves tutelage to breast not only the scientific applications of that particular date, but to follow for herself professional developments of the future which shall depend on science. That ensures a progressive practitioner instead of maybe a reactionary one. I wish some time could be found in the curriculum for the teaching of the principles of scientific psychology.

And with regard to the sciences dealt with later in the curriculum, they are a part of medicine itself. Differentiated as they are necessarily and dealt with by separate specialist teachers, it is to be remembered that they are from the point of view of medicine essentially one, although separately designated. Therefore, as you study them the more you make them overlap and interlap—histology, anatomy, physiology, biochemistry, bacteriology, pathology—the better will you grasp all and each. Of reasons why that should be so, one is that disease is but disorder of health. Over and over again the normal and the abnormal merge one into the other by degrees practically imperceptible.

The Meeting of Science and Art.

In medicine, two aspects—namely, those of science and art—meet; at their extremes they are clearly distinct, but their mutual boundary is untraceable. As to what science is and what art is, let me take refuge in saying that all definition is notoriously difficult and that comparisons are odious. Bandaging, I think, I have seen in some hands an art and not a science, and yet in others both an art and a science; and possibly in others a science but without art. Science pursues knowledge for the sake of knowing the how of a result. Perhaps Art uses knowledge for the sake of a result without caring about the how. Science has laws, which, unlike some laws, are unbreakable. Hence Mr. Bateson's wise advice, "Cherish your exceptions." In Nature every seeming exception is but obedience to another law. With Art laws are on another plane—even in the fine arts. The laws of the romantic school of yesterday were not the laws of the classical school of the day before. The laws of the Cubists to-day will not be the laws of the Futurists, perhaps Polygonists, of to-morrow. Hence medicine which has become scientific is more stable than medicine which has not. Fashions of bandaging may change, but the principle of asepsis abides. Science and art dovetail in medicine; that is the real point of importance, not any impossible attempt to distinguish them minutely. Art where skilfully efficient unconsciously adopts measures science would endorse. And it is a mistake to suppose, as seems sometimes done, that the divisions between science and art in medicine correspond with division between the laboratory and the ward. Science can enter into the handling of a case in ward or out-patient room as fully as into laboratory observation or experiment. Last year the Harveian Oration by Sir Archibald Garrod and Sir David Bruce's Presidential Address to the British Association in Toronto pointed out that medicine, while owing much to science, has also given to science immensely. In medicine the clinical and the laboratory studies support and fructify each the other. They flourish together or but little. But the finance of both is difficult, and especially, I think, for the laboratory. Higher education belies the old precept that a venture which deserves success will pay its own way. Higher education never pays its own way. It is said that American colleges spend on each medical student £100 more than the fee receipts. Such a situation endorses and commends the appeal made by this school for a fund to endow some of its laboratory professorships, anatomy, physiology, and pathology. This is a University school, and its laboratories are in that sense University laboratories. Distinguished teachers direct them. Endowment is necessary for such Chairs. The eloquence of the circumstances ensures the success of the appeal; and I hope quickly, for the need is urgent. A fine lead was given last year by devoted friends of the school, including Lord Riddell, who has also so generously helped the hospital itself. And help for the physiological laboratory has come from the Augustus and Alice Waller Memorial Fund, a memorial especially appropriately connected with this school and with research. The laboratories of the school have already won repute as places of research. An element for success in research is the putting the right question to the problem. The astounding research capacity of Pasteur himself lay perhaps as much in asking the right question as in his genius for developing and ripening the latent possibilities of laboratory means. Splendid intention is futile if for the question it puts the time is not yet really ripe. This must be borne in mind in the coöperation for research between laboratory and clinic. Experience shows, I think, that with laboratory and clinic each puts its own question best, knowing its own best means. Both can have a common problem, as in the recent success with rickets, and both can have a common strategy; but the tactics of the two are better independent.

Men and Women in Medicine.

Increasingly noticeable in medical research is the tendency towards team-work—a change probably impressed by experience in the late war. In a research team each member takes one part and all parts simultaneously conspire towards a single aim. This plan seems destined to replace advantageously the individual less coördinated effort toward medical discovery in the past. Coöperation is a proper and happy counterpoise to the competition which is perforce so large a rule in life. Team-work accomplished the glorious cathedrals of a former age; in an age of scientific medicine it may rear spiritual edifices no less glorious. I fancy women combine readily for team-work, and are specially fitted to play in it an eminently important rôle, and preferably in coöperation along with men. The very contrasts between man and woman help each to eke out and amplify the powers of the other. Galton arrived at types of family physiognomy by compounding photographs of individual faces. To combine in that way faces of women and men doctors might yield a composite prophetic picture of the ideal physiognomy of the profession. Not that physiognomy consists in features of the face alone. Craniums also can, of course, be long or round. There are, as we all know, modest shoulders and shoulders that are arrogant, elbows egotistical or accommodative. These all both in man and in woman. Woman and man are not wholly unlike. There is something of man in woman, and something of woman in man. The existence of this school and its success show, I think, that woman's due and right place in medicine is won not by her aiming at man's particular qualities, but by her using and training to medical purpose the gifts of her own womanly nature. To me seems regrettable the London County Council's recent regulation that married medical women are ineligible for its medical officerships. I have seen it estimated that about 30 per cent. of medical women marry. That, however, is a lower percentage than is obtainable from the list of former students of this school.

The cause for which this school stands is assured. That women should enter medicine and practise it is but a further and most natural evidence of what we have been talking of—the progress of medicine. But those who go first often have to walk somewhat lonelily, and find their path less free than those who follow. This school does well, therefore, to remember with pious honour those who led the way. Social adaptations come slowly. An elder generation tends to hug old opinions. Truly progressive cannibals eat, it is said, their oldest relations. But I am not sure that that is a complete remedy. Reform is rarely facile. It is not, as Rousseau taught, a simple return to nature. Perhaps, like the ancients, he thought us descended from the gods. But after him came Darwin. It is a long ascent from the grimaces of the ape to the smile of Monna Lisa. But one sex has accomplished it, and it speaks to the comfort of both. A mere man, I have myself had homely reminder of mental kinship to primitive forbears. When my laboratory kept chimpanzees I used to pay a daily visit to them at large in their room. Once after such a visit, when I had just left and locked the door, I turned back again, pondering what the chimpanzees might do when I had left; I stooped and looked through the keyhole. A chimpanzee's eye met mine peering through the keyhole. The same thought had struck us both, both her and me—she, as a lady, had acted first. When the human community about you seems slow in development, recall my case. Surely it is encouraging that despite my mental resemblance to simian stock the convincing logic of your cause stands plain even to me.

The Traditions of a Medical School.

But to return to this school with its tradition of noteworthy names in the past, and no less noteworthy still with it. One of the things that it has proved is this: that women are well able to fulfil the expanded social duties it trains them for. And the fulfilment of those duties involves more than solely the science and the art of medicine. Every case of sickness is as well as a problem for medical science and art, a fellow creature's suffering. Of all grounds ever taken surely the strangest is that of the man who when refused by a young woman resolved to enter medicine in order to harden his heart. The impression, if it exist, that medical routine tends to blunt feeling is wholly mistaken. Egotism may harden the heart, but knowledge never. Character is what counts. Medicine enhances compassion and instruments it by giving it further resources wherewith to help and comfort a sufferer. As to the danger from the alleged coldness of intellect, as medicine leans more upon science, pure science, it is true, is intellectual, and pure intellect is somewhat like that supreme instrument arisen from it, mathematics, which works best with the abstract—in vacuo, so to say. But at the bedside the "case" is always concrete, and rescues feeling. Moreover, though science may be infallible, not so its votaries, as none know better than they. Science then teaches humility, and humility is close to sympathy, and one essence of successful medicine is sympathy armed with understanding. Sympathy armed with understanding, that surely is a trait that medical women stand for. To those who possess that, what opportunities does not medicine afford of beneficence to the community. To those who by reason of enthusiasm for medicine are entering upon it here, I would affirm that their enthusiasm is well founded. I trust I have not kept you too long in arguing towards so self-evident a conclusion.

An Address
ON
TRADITION IN MEDICINE.

Delivered at the Opening of the Winter Session of the Middlesex Hospital Medical School

By C. E. LAKIN, M.D., F.R.C.P. Lond., F.R.C.S. Eng.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

There are three days in a physician's life which may be said to be unique. There is the memorable one upon which he is elected to the staff of his hospital, a day of unalloyed happiness and pleasure; then there is the day of gloom when the time limit sounds his departure from the activities of the hospital; and the third is one like to-day when he gives the introductory address and feels rather like the mariner about to cross the equator for the first time, hardly knowing whether he is quite likely to enjoy all that Father Neptune has in store for him, whether the crowd of onlookers will be sympathetic, and whether his performance may not end in catastrophe. Still it is the tradition of our hospital that this must be faced, and in confronting it one is naturally brought up against the question: What is there in tradition that it should have such a powerful hold upon us?

We are living in an age of rapid transition and of suspended judgments, and those who are familiar with Chekhov's Cherry Orchard, in which is seen depicted the pathetic inability of the older generation to cope with the pressing circumstances of the present, may well ask. But is not tradition crippling us on every side? One must freely admit that there are elements of danger in tradition, but that is not to concede that tradition itself is valueless. Without it chaos replaces order and experience never attains fruition. Each generation must be provided with a starting-point and for this continuity with the past is essential. But tradition itself is not stationary, it is always suffering change. Although at any one moment it may be said to be fixed, at the next it is not quite the same. It is in some degree subject to flux and possibly in increasing degree with the passage of years. It may be observed that the human mind, on the other hand, tends to become less elastic as our years creep on. With few exceptions the older we become the more conservative tends to be our outlook. To such an extent is this true that some see in this very fact the necessity of death in the economy of Nature. Death is Nature's way of evading stagnation.

Now the danger of tradition is found in its power of establishing a prevailing opinion which in itself is antagonistic to further advance. As long as the chief place in medical tradition is assigned to observation, experiment, verification, and induction, this danger is but slight. Medicine has no creed as such to preserve. Its system of knowledge is but the accumulation of facts which have been ascertained by the application of the scientific method to the study of the body in health and disease. By scientific method, if for one moment I may labour the point, we mean observation, experiment, and verification. It has been well said that the mind of Sydenham, interested in a sick child and humanely pre-occupied with its cure, did not, in so far as it functioned scientifically, operate differently from that of Galileo interested in the movements of the earth. Both alike reflected, verified, and generalised.

But tradition is more than medical lore and the sum total of medical science. Just as in another sphere we talk of a manner of living or way of life distinct from life itself, so in medicine there is a setting in which medical knowledge is enshrined. This is as difficult to describe as is the tradition of a public school or the esprit de corps of a regiment. Like so many of the finer things in life it evades explanation and vanishes into thin air as soon as one tries to take hold of it. It is this elusive atmosphere of which I would attempt to speak to-day to those of you who are about to start your medical studies. To dissect so subtle an influence were almost impious, but if we attempt it hero-worship, historic association, love of beauty, truth and goodness, and the tears and strivings of men will all find a place there.

Who can remain unmoved by the story of William Charles Wells? Wells was a medical man, who like so many others at the beginning of the nineteenth century, had taken to medicine as a means to a livelihood, in order to devote his spare time to the physical sciences. For save in mathematics there were practically no university chairs or emoluments in England open to students of biology, chemistry, or physics. In what follows I borrow freely from the account which Dr. Arnold Chaplin gives of Wells in his FitzPatrick Lectures, delivered before the Royal College of Physicians in 1917–18. Wells began his career in London penniless, and after 16 years of toil was unable to command an income of more than £307 from all sources. Ill-health dogged his steps, and in his forty-third year he was seized with a slight stroke and henceforth it was a grim fight against time to finish the work he had designed. In spite of these disadvantages he laboured on bravely in his humble lodging in Serjeant's Inn, known to few save five close friends, among whom were to be counted Matthew Baillie, David Pitcairn, and David Hume. The name of Wells will be for ever honoured, for he succeeded in investigating and establishing the laws which govern the formation of dew, leaving little to be added by subsequent research. Wells carried out his experiments in the garden of a Mr. James Dunsmore, a merchant friend of his, who lived in Surrey, three miles beyond Blackfriars Bridge. Thither Wells betook himself in the late afternoons, and using pieces of wool of known weight, weighed them again after they had absorbed the dew in various situations and under varying conditions of atmosphere. It is a melancholy picture, this last effort of his, labouring to finish his experiments by night in Dunsmore's garden and trudging home with dropsical legs in the early morning hours to record his results lest death should claim him ere his task was ended. Surely few investigators have battled more bravely with adverse conditions. When his work was accomplished he desired only the modest epitaph, "He tried to extend the bounds of knowledge."

> "Man with his burning soul
> Has but an hour of breath
> To build a ship of truth
> In which his soul may sail.
> Sail on the sea of death,
> For death takes toll
> Of beauty, courage, youth,
> Of all but truth."

Of such stuff is medical tradition made. Wells's medical investigations were chiefly concerned with dropsy and uræmia and have scarcely received the consideration they deserved. It may be remembered that Charles Darwin, in his historical introduction to the origin of species, gives to Wells the credit of having been the first to enunciate the principle of natural selection in a paper read before the Royal Society in 1812. The names of Thomas Young and William Hyde Woollaston occur to us as other instances of physicists who have practised medicine. Young, who was responsible for the undulatory theory of light, it is interesting to note, lectured in our hospital before the school had been founded by Charles Bell. There is a letter of Bell's which I feel I cannot pass by in silence, giving a picture, as it does of his early days in London:

"Coming to London with the resolution to fix myself here was certainly a desperate measure, for I had formed no friends, and absolutely did not know a human creature, When I consider the few introductions I had—to men who could be of no assistance to me—I look back with something like a renewal of the despair I then felt. My first object was to introduce myself to the several schools, with the expectation of being taken as an assistant by one or other of the chief teachers. Cline and Cooper were lecturing in the Borough; Abernethy, with his assistant Macartney, in St. Bartholomew's; Sir William Blizzard and Mr. Headington in the London Hospital; and Mr. Wilson in Windmill-street, in the school of the Hunters.

"I could see that a great deal was to be done, but where to find a resting-place? How show my capacity for teaching or illustrating my profession?

"These days of unhappiness and suffering tended greatly to fortify me, so that nothing afterwards could come amiss, nothing but death could bring me to a condition of suffering such as I then endured. There was a little romance with it too. I found myself so cut off from the society I should have wished to cultivate, and which I thought I deserved, and so alone in this world, that I entertained myself with fancies as to what set of people, and what family, and what place, it was likely Providence was to unite me to.

"In short, I believe I was as romantic as any young man could be, although the prevailing cast of my mind was to gain better celebrity and independence by science; and perhaps this was the most extravagant fancy of all.

"I never thoroughly hated London while I could lose myself in it. I had a pleasure in wandering through streets I did not know; but at last it appeared to me to consist of insignificant parts almost infinitely multiplied.

"I was not idle, however, all this time. I had a subject of study always with me. I was preparing my Anatomy of Expression, and made some anatomical studies in the Westminster Hospital.

"I could not help regretting the noble fields that were everywhere around me for exertion in my profession, and which I found closed against me.

"One night I resolved to return to Edinburgh. I went to the opera, to leave the last pleasant impression of London. I could dwell upon my feelings of that night, but few could sympathise with them, and next morning I resolved to remain in London. I took a large ruinous house in Leicester-square, formerly inhabited by Speaker Onslow. When I went with my surveyor to examine it, I was somewhat appalled by his account; he was a great John Bull rough fellow. Leaning out of the window, and observing the walls out of their perpendicular, he said in a coarse familiar manner, 'Sir, you had better have nine bastard children than this house over your head.'

"In taking this step I was conscious I must withdraw myself from such society as I could have loved, and here I gave myself up exclusively to the teaching of anatomy. Such were my miscalculations, that my expectations of a large class were sadly disappointed. It was years before I had 40 pupils to lecture to.

"When I got into this house, the first night I slept in it I had put out the candle and was leaping into bed, when the floor gave way under my foot, and I found I had displaced the board. On examining this in the morning I discovered a tube under the loose board—it was the house where the Invisible Girl exhibited!

"A man brought up as I had been in Scotland has certain notions of respectability, which are very strong and very peculiar. I don't know that at any time I was more depressed than when I found the sort of house I had got possession of, but it was one of those absurd errors into which a stranger in London falls. Before taking it I had been provoked with the opinion of everybody I consulted about my plans, their lowest estimate being that of £10,000 to set me agoing. Even yet I am not rich enough to boast of my poverty."

While medical tradition transcends all geographical boundaries it is in our hospitals and medical schools that she has her special dwelling. A hospital and medical school is something more than a block of buildings where instruction is meted out to students. At Middlesex I have sometimes thought that I have caught sight of the genius loci—the prevailing deity—on the way up to my wards. He is an old man with a white beard and wrinkled face, but in his eyes is the twinkle of perpetual youth. He has usually been standing at the turn of the staircase or on the landings, and as our little procession to the wards approaches I have seen him put his fingers to his lips while all his attention is given to those behind me. It is as if he is picking out his votaries to entice them into his realm, to study with him clinical medicine in the wards of the hospital.

If the blood of the martyrs is the seed of the church, the devotion of the hearts and minds of Middlesex students is the glory of the school. A medical school is not a technical school, and it is because I wish those of you who are joining us for the first time to-day to know something of the spirit of the place that I have been speaking in the way I have to-day. Some of you have come from the older Universities and may, like the scholar gypsy, have walked by Godstow and Bagley Wood, and, unlike him, in high talk have discussed all things in heaven and earth, plumbing the depths of speculation in a world where speculation rightly takes the place of experience. Here, you are suddenly, perhaps too suddenly, brought face to face with reality and your university education continues with a difference. Take note of the motto of your hospital *Miseris succurrere disco*, and in learning to help the wretched you will see that you yourself are undergoing development. Read the legend over the entrance to the post-mortem room, *Hic locus est qua mors gaudet succurrere vitae.* Here is the place where death rejoices to help life and you will come to appreciate the amazing healing power of Nature even to the last. Scorn delights and live laborious days and you will find the world of knowledge has its enchantments. It is not the platform but solitude where true work is done, and I never tire when I feel that we are becoming a little Americanised of thinking how from a small ward of nine beds, with no special facilities, Vesalius taught surgery to Europe. Thank heaven! medical tradition at any rate has nothing to do with propaganda, publicity, and newspapers!

Do not be discouraged by the exactions of the profession you have chosen. The more conscientious may ask: Ought I not to let everything go save my immediate studies, since to me are to be entrusted the lives of my fellows? The question is sufficiently plausible, but the answer is emphatically No. You must first be a man and then a doctor. You must learn to live in the present and to understand the entourage and mental outlook of your patient, and how will you do this if you become simply immersed in study?

Middlesex man as I am, on an occasion like the present, I cannot end without paying homage to those of my friends and yours who so nobly upheld our hospital traditions in the late war. In dying they put on immortality, being silent they yet speak, and have left behind an imperishable memory that needs no memorial:

"Sons of this place of you let it be said
That you who live are worthy of the dead,
These gave their lives that living you may reap
A nobler harvest ere you fall asleep."

Spa Treatment for Panel Patients.—At the autumn meeting of the British Spa Federation held last week at Woodhall Spa the question of spa treatment for insured persons suffering from rheumatic diseases was further considered. British spas are, it is stated, unanimous in their desire to see the benefits of mineral water treatment made available for those who have hitherto been unable to afford it, and a special subcommittee consisting of representatives of Bath, Buxton, and Harrogate was appointed to work out practical details satisfactory alike to the insured patients and their doctors, and without interference with the routine and comfort of the ordinary visitors.

Leeds Voluntary Hospitals Committee.—This newly formed committee has already induced 1085 firms in the business centre of Leeds to join the scheme; a further 3000 have still to be heard from. The promises of subscriptions thus obtained aggregate close upon £7000. A large number of insurance companies and companies owning multiple shops have refused to come in, on the ground that they have so many branches in different towns that to subscribe to the local charities in each would constitute a heavy drain, and that they could not subscribe in one place and not in another. It is, however, felt in Leeds, and probably in other towns, that firms who drive out local shopkeepers who were subscribers to hospitals ought to be prepared to "pay their footing."

An Address

[ABRIDGED]

ON

THE MEDICAL CAREER.*

By Sir HERBERT F. WATERHOUSE, M.D. Edin., F.R.C.S. Eng.,
CONSULTING SURGEON TO CHARING CROSS HOSPITAL.

[Sir Herbert Waterhouse began by saying that for over 33 years he was a member of the staff of the hospital and of the medical school. During that time, at various periods, he held every position open to a surgeon and also those of dean and of chairman of the medical school and the hospital, and its branches were amongst the greatest interests in his life. The school was to be warmly congratulated on its present Chairman, Sir George Verity, whose success in freeing the pathological department from debt was already sufficient claim for gratitude. He continued :]

I can honestly congratulate you on your choice of a profession because you have chosen one in which you can help your fellow men and women, can lessen their burden of sorrow and suffering, can earn their esteem and affection, and can assure yourself of a fair competence when the time comes for you to retire from practice. If riches had been your quest you would have gone in for trade, certainly not for medicine. In joining the medical profession you can, at the most, expect moderate financial success, but this is, I am convinced, more safely to be reckoned upon in the profession of medicine than in any other of the great professions. The sick we have with us always and there is ever work for a good doctor. We have nothing comparable to the briefless barrister or to the clergyman, who, though an old man, still remains a curate. But if an adequate reward for your labour may fairly be expected in our profession, your preparation is far longer and far more strenuous and exacting than that for any other profession. You will, for the next five years or more, have to "scorn delights and live laborious days" if you are to attain that standard of knowledge of your professional work that alone can fit you to take charge of the lives of your fellow men and women. In some other professions a fair amount of knowledge may suffice to ensure success; in ours nothing short of the best is justifiable; the stakes for which you play are human lives, sacred in the sight of God and man, and this is the day on which to determine that you will do your utmost to fit yourselves for your high calling.

The school you have joined will do its part to help you, and, if you equal the record of the best students of this school in recent years, you will have every reason to congratulate yourselves. Within four years I was fortunate in having as my house surgeons three of the most brilliant young surgeons I have ever known—Messrs. W. S. Fenwick, Norman Lake, and C. J. Marshall—all Charing Cross men. Among the distinctions gained by this brilliant trio were two gold medals at the final M.B., B.S. London examination, one gold medal and one qualified for the gold medal at the M.S. London, one gold medal at the M.D. London, the degree of D.Sc. London, and the Murchison prize in clinical medicine.

I doubt if any medical school in London ever, in so short a period of time, produced three abler men. Mr. Fenwick, to our extreme sorrow, was forced by ill-health (now happily recovered from) to leave us, but Messrs. Lake and Marshall fortunately remain and both are sure to add further to the reputation of the hospital and of the medical school.

It is a pleasing fact that, in the study of medicine, each succeeding year is less of a drudgery and more interesting than the previous year. During your earlier years you will find the study of anatomy wearisome and dissecting somewhat unpleasant. I urge you not to neglect this very foundation of professional knowledge. A good knowledge of anatomy can only be acquired in the dissecting room, and careful dissection alone will teach you how to find your way about the human body. One of my old teachers used to say that surgery is merely "common sense applied to anatomy" and there is more than a germ of truth in this dictum.

With regard to the subject of lectures you will hear it stated, not infrequently, that lectures are useless. I certainly do not hold this view, though I admit that I thought they were over numerous in my student days. The greatest merit of the 9 o'clock lecture is to compel an early start, and I would advise you to keep your reading always a few days ahead of your lectures. If you hear a lecture on a subject which is new to you, you will of necessity fail to assimilate many points. If you have read the subject up a day or two previously you will derive infinitely more benefit from the lecture. It is only when you start your clinical work at the hospital that you will begin to appreciate the real fascination of the study of medicine. Your earlier years of study will have been the somewhat tedious preparation for the foundation of your clinical knowledge and you will now be entering on your real life's work. I would advise you to attend your physician and your surgeon in all his visits to the hospital; the student who flits from one clinical teacher to another will doubtless learn much of value, but he will not see the same cases treated throughout the whole of their stay in hospital, and will not attain the same personal knowledge of disease and its treatment. If you are constant in attendance upon the teacher of your choice, you will, insensibly, follow him in his mental processes and will find yourself doing almost instinctively what he would do in like circumstances. I can speak from experience. I had the good fortune to be house surgeon to one of the greatest surgeons of all time—the late Sir William Macewen. For six months I studied his great intellect as closely and as devotedly as I was able to do, and, in later years, I have often found myself doing something almost instinctively, and, when I pondered over the question, I found that I was following the example of my great master.

During your final year I would urge you to devote particular attention to the special departments, particularly to those for diseases of the eye and of the throat and ear. These important branches of surgery are usually neglected by students to the detriment of their patients in later years. These remarks apply particularly to diseases of the eye, in some of which a few hours delay in instituting appropriate treatment may result in permanent damage to the sight. It has been said that the fear of examinations is the beginning of wisdom for the medical student. If every surgical examination paper contained a question on diseases of the eye, throat, or ear, these important subjects would soon cease to suffer neglect. As soon as you have qualified and registered, you will do well to join one of the medical defence societies. While you will find the large majority of your patients grateful and appreciative you may come across one who is cantankerous and inclined to litigation, and such persons have no difficulty in finding solicitors to encourage them. They seem to expect that bad fractures into joints should always give perfect results and, if they are disappointed with the issue, they blame, not the injury, but the unfortunate doctor. Such people do not sue their lawyers or stockbrokers when their advice has turned out badly. They seem to specialise in actions alleging negligence against their medical adviser. I have, for some time, been a Vice-President of the Medical Defence Union, and can tell you that 30 members, on an average, seek advice and assistance of the Union at the meetings of its executive, frequently after the receipt of a lawyer's letter alleging negligence. The vast majority of such complaints have no foundation and are disposed of without further trouble. Everyone makes mistakes except the fool and the liar; the former cannot see his mistakes and the latter denies them. In any event it is a great relief to know that you have behind you powerful support and protection, and that you are insured against any possible financial loss in the unlikely event of a verdict being given against you. From close personal knowledge I beg you not to neglect to join immediately one of these protection societies.

---

* Delivered to the students of Charing Cross Hospital at the opening of the Winter Session.

Next, I strongly advise you to try to obtain a resident appointment as house surgeon or house physician (or preferably as both) in your own hospital, or, failing that, in another large institution. It is impossible to over-estimate the value of such a post. Not only will you see a large number of interesting cases, but you will have the advantage of making your diagnosis and of forming your opinion as to how each case should be treated, and then of having your views confirmed or corrected by your senior officer. I have never known anyone consider as wasted the time spent in holding resident hospital appointments, but I have, over and over again, heard men regret that they had failed to take advantage of the opportunity of obtaining such posts. Having, as I hope, spent a profitable year as a hospital resident, I would now urge you to study, for at least one session, abroad. When I was a student, in the late 'eighties, it was a very usual thing for a recently qualified medical man to devote several months to study on the Continent. I had the good fortune to spend a winter session at the University of Göttingen. This time of foreign study widens a man's mental outlook and helps him to get rid of many of the traits of our insularity. I found it most helpful and would earnestly recommend it to your attention. It is, moreover, an enormous advantage to a medical man to have a sound knowledge of French and of German. I have read most French surgical text-books and several in German, and I can testify to the advantage I have derived from them. I would advise you, throughout life, to continue your study of these two languages, so important for scientific medicine.

If you follow out the course I have above indicated you will be well equipped for your life's work.

Some of you will, doubtless, strive to become specialists, but the large majority will be content with the rôle of general practitioner, and the really good general practitioner is the highest development of our profession. It is comparatively easy to know practically all that there is to be known about one branch of medicine. It is far more difficult to know, as some first-rate general practitioners with whom I am acquainted certainly do know, almost as much about every branch.

Among my personal friends two of the ablest are general practitioners in South Hampstead. One is a doctor of literature, of laws, and of philosophy of the University of London, in addition to holding a doctorate in medicine. The other is an M.D. London, F.R.C.S. Eng. On the many occasions I have met my two friends in consultation, I have always felt that they knew about as much of surgery as myself and more of every other branch of medicine. I can safely say that I have learned from them far more than they can have learned from me. If these able men are content to remain general practitioners you may well be so.

For what are the requirements that go to make first-rate general practitioners? There are three desiderata: (1) A thorough knowledge of medicine in all its branches; (2) the faculty of inspiring confidence in your patient; and (3) sympathy.

Granted all these three, a successful and beneficent career is a certainty, and lack of any of them will gravely hazard your usefulness. Obviously the most important is the first, but the faculty of inspiring confidence is an essential requirement, and is most helpful to your patients.

How often do we not hear it said: "I have no confidence in Doctor X." Or: "Doctor Y has assured me that I shall pull through all right, so I am quite happy." Poor Doctor X and fortunate Doctor Y. The latter may have less knowledge than the former, but he has his patient's confidence, and that, in many cases, is so often half the battle. We all know men who inspire much confidence and deserve little; men, who, judged professionally, would be weighed in the balance and found wanting—and we know, also, men of brilliant intellect who can make no real headway in practice because they lack this faculty to inspire the confidence in their patients. It is partly a gift, but it is a gift, in a large measure, capable of development. I wish to impress upon you that before you can expect to inspire confidence in others you must have confidence in yourself, and this can only come with knowledge. If you have full confidence in your diagnosis and treatment it will be easier to impart this confidence to your patient. Strive always to gain the confidence of your patient, even from the time you are a dresser or clinical clerk. If you succeed with the charwoman from the slums you will not fail later with the countess in Mayfair. I would venture to urge upon you the importance of learning to express your opinion shortly and to the point. Nothing will help you more to attain this object than joining in the discussion of your medical and debating societies. Here you will learn to say what you have to say clearly and accurately, well knowing that you will not escape criticism from your fellow students should you fail to do so. In this way, as in many others, you will find the best of your fellow students among your best teachers. Remember always never to treat your patients as if they were fools. The vast majority of them are not, and they, during their time of illness, have plenty of leisure to ponder over what their doctor has said to them. The danger of being too chatty is that you may forget what you have said on a previous visit and may say something that may seem to contradict a statement previously made by you. When you are certain you are right say little, when uncertain say less.

Sympathy is the third of the desirable qualities that go to make up my ideal practitioner of medicine. It must, however, be sympathy combined with firmness, and mere sentimentalism is of no use. You should convey to your patients not that your heart bleeds for them, but that you are genuinely interested in themselves and their maladies; that, for the time being, theirs is the most important case you have under treatment; that you mean to devote your best endeavours to its cure and that you bring encouragement and hope of recovery from the illness. But blend your sympathy with firmness and decision, and remember that kindness and tenderness are duties that strength and health owe to frailty and sickness.

I have now come to the end of my advice to the new entrants, who are starting on a journey that is strenuous and exacting. Some, but I hope very few, will fall out by the way, but be certain that patient, intelligent effort will always be successful. The medical profession is one which offers joys that are worth gaining and that no other can afford.

ALEXANDRA DAY.—The collections on Alexandra Day (June 10th) produced £45,088, and the expenses to £7635, £5940 of which was the cost of the roses made by cripples. Queen Alexandra has earmarked £10,419 for institutions in which she is especially interested, and £27,555 will be distributed among various hospitals and charities.

THE LATE R. T. HUGHES.—Robert Thomas Hughes, M.R.C.S. Eng., L.R.C.P. Lond., formerly in practice in Higher Tranmere, died suddenly on Sept. 28th. He studied at Owens College, Manchester, and at University College, Liverpool, and qualified in 1895. He was medical officer of the Birkenhead Union and one of the best known medical men in the Tranmere district. He was a Lieut.-Colonel in the R.A.M.C. (T.) and saw lengthy service during the war. Dr. Hughes was in his fifty-third year and leaves a widow, four sons, and a daughter.

STABLE NERVOUS CONTROL IN RELATION TO FLYING EFFICIENCY.*

BY MARTIN FLACK, M.B., CH.B. OXF.,
GROUP CAPTAIN, ROYAL AIR FORCE MEDICAL SERVICE.

(*From the Medical Research Laboratory, Royal Air Force.*)

A MEETING such as this affords opportunity for discussion of the conclusions reached by those who for several years past have been concerned in the study of the human machine in relation to flying. No doubt, considerable difference of opinion may exist as to what are the chief characteristics which make for efficiency as a pilot, and, in consequence, on the best methods to be employed for the selection of personnel for piloting duties. It may be that such difference of opinion, if it exist, is due in part to difference in racial temperament and so forth, therefore it is not suggested that the conclusions formed in respect of the British are necessarily applicable to pilots of other nationalities. Such a conclusion could only be definitely reached if the same characteristics were found in the exceptionally fit and able pilots of all countries. The method of investigation pursued in Great Britain has been to study the characteristics of the most satisfactory pilots selected by the executive, and to contrast the results so obtained with pilots who have not been so successful or who have definitely been unsuccessful.

The main point of this paper will be to emphasise the fact that all-round success in flying is definitely associated with stability of nervous control, particularly of subconscious nervous control, and that in the selection of personnel for flying duties particular attention must be paid to this point.

Under the term "all-round success" we may group: (1) ability to acquire the art of flying; (2) physical and nervous endurance for repeated flights at high altitudes and flights of long duration; (3) flying temperament, which it is not proposed to discuss here.

Visual Efficiency.

In acquiring the art of flying the sense of vision and the power of correct neuro-muscular coördination of the limb muscles are of the greatest importance. In respect of vision the point on which it is desired to lay the greatest emphasis is the fact that binocular or better "bifoveal" vision, the term suggested by Sir Arthur Keith, is of the greatest importance. Such vision cannot be obtained unless there exists good balance of the eye muscles. Although this balance may in a large number of cases be destroyed by occupations which call largely for the use of one eye—e.g., close instrument work—microscope, sextant, slide-rule, &c.—it is even more important to recognise that in certain candidates there exists a lack of eye muscle balance which has no such cause, but is in reality an expression of unstable nervous control of the eye muscles. This instability is of great importance, particularly when associated, as it very frequently is, with other signs of subconscious nervous instability, since the subject is unlikely to fly successfully. He will be prone to erratic landings and is likely to break when exposed to hard work. The above conclusions are based on the excellent work of Wing-Commander Cecil Clements, of the Royal Air Force Medical Service, who, in suitable cases, has been successful in correcting this defect by special ocular muscle exercises, thereby converting erratic landers into successful ones.

Muscle Sense.

As experience in flying grows, the pilot, in addition to employing the sense of vision, relies also for the formation of judgments upon the "feel" of the control column, rudder bar, and seat. These sensations have their origin in impulses from the muscles, joints, and tendons. Not only do such sensations aid the pilot in forming an idea of his position to the machine and the nature of the evolution which it is executing, but upon these nervous impulses arising from the muscles, joints, and tendons depends the harmonious and smooth functioning of the muscular groups by means of which the pilot exercises control of his machine. The importance of these proprioceptive stimuli in relation to flying has not altogether been fully appreciated. Next to vision, therefore, these sensations are of the greatest importance to the flier. Such was adduced by the careful questioning of pilots, in respect of the sensations by which they fly, but the work of Garten has demonstrated the fact experimentally. Garten found by the use of a tilting chair that when blindfolded and at rest (in contrast to the rapid movements of an aeroplane), the main source of information as to our position in space was due to deep muscle sensation. All people are not endued with the same sensitivity of perception, but deaf-mutes were equally as expert as normal individuals. When the weight of the body was removed by immersion up to the chin in water, the sensitivity of perception was greatly decreased. Strong cooling of the skin of the heels and soles of the feet, and in one case injection of novocaine, caused no falling off of accuracy of perception of tilt in the tilting chair.

These experiments indicate that the so-called otolithic functions of the semicircular canals exert but little effect in affording information as to our position in space, although it is not denied that their integrity, whatever be their exact function, is of importance for aerial work, probably for the exertion of steady subconscious neuro-muscular control.

Tests for Muscular Coördination.

To judge whether a man has sufficient coördinative skill of the limbs for flying, actual flying is undoubtedly the real test; but this is expensive, involving much waste of instructors' time as well as damage to machines. In this respect, however, a certain amount of guidance can be offered by the medical side, but it must be made clear that the mere testing of psychomotor responses is not in itself sufficient. Although such tests have value—that is, a steady stable response is good and an erratic unstable response is bad—too much attention cannot be paid to the results, since the manipulative effort—raising or depressing one finger—bears no relationship to the manipulations of flying, and since, also, the coördination of eye, hand and leg, which plays so important a part in the control of the aeroplane, is not adequately tested. In England it has been found necessary to devise an apparatus which records the time taken to perform the actual arm and leg movements made in flying—as, for example, the time taken in response to a visual stimulus to bring, by the appropriate movements of the control stick and rudder, a stationary aeroplane out of what in flight would be a "spin." In this way a test is made of the time of response to both exteroceptive and proprioceptive stimuli, and an estimate formed both of quickness of perception and delicacy of the coördinated movements of flying. The apparatus was evolved by Flight-Lieutenant G. H. Reid, D.F.C., from his original control indicator designed for the purpose of night and fog flying, which is being described elsewhere at this Conference. A report upon the use of this apparatus for testing flying aptitude has already been published in the Proceedings of the Royal Society of Medicine, vol. xvii., No. 12 (Reid and Burton).

The method of investigation is as follows:—

The subject is seated in the machine and the mechanism explained to him. A preliminary series of trial reactions is given, and, when the idea of the test is grasped, observations are made as follows:—

1. Time taken for successive hand movements from right or left to central position.
2. Time taken for leg movements on the rudder to central position from extreme right or left positions.
3. Time taken for combined movements of hand and feet simultaneously—usually from stick back and full over

---

* Being a paper read to the International Congress of Aerial Navigation at Brussels on Oct. 7th.

to left side with rudder full over to the right side—a position corresponding to that obtaining in the spiral manœuvre known as a "spin." In this case the time is taken until both controls are exactly centralised.

The effects of distraction may be observed by sounding a Klaxon horn unexpectedly during a series of observations. The effect is noted, not only upon the actual time of that response, which may be increased, but particularly upon the succeeding responses. A marked increase in reaction time persisting over several responses after the noise suggests some instability of nervous control. According to the individual the time taken for the centralisation of the rudder control is from 0·5 to 2 seconds, that of the stick from 1·5 to 5 seconds, due to the greater sensitivity of the setting of the stick control in the apparatus; that of the combined manœuvre (hand and feet) from 2 to 10 seconds.

These observations bring out the following points:—

1. Comparison of the time curves of hand and feet taken separately.
2. The comparison of the curve of simultaneously combined hand and foot movement to those of each taken separately.
3. The actual speed of reactions of each type as shown by the ordinates in the graph.

With this apparatus it has been found that:—

1. The first-class pilot gives a consistent record with an average time about two to three seconds, varying according to the type of machine and number of hours flown.
2. Those found unsuitable for instruction give curves of a multi-peaked nature, showing markedly erratic responses with, generally speaking, a big average time, five to six seconds.
3. The subject suitable for training, although giving a longer average time—four to five seconds—displays consistency of performance, although markedly erratic responses of long average duration probably indicate an inaptitude for the coördinated movements of flying.

It is not suggested that this apparatus shall be used on one occasion only, as, for example, at the entrance medical examination. It should preferably be employed during instruction in flying, when periodic tests will afford indication as to the rate of progress and of likelihood of acquisition of flying skill. It seems probable also that the apparatus may prove of service as a means of training pupils to acquire on the ground those particular coördinations necessary for control of the aeroplane in the air. Possibly also the apparatus may afford indication of the particular type of machine for which a pilot is especially suitable—fastness of time combined with stability indicating, for example, an aptitude for scout machines.

Physical Endurance.

But for flying efficiency it is not enough (as was shown in the war) to be endowed with a mechanical and mental aptitude; it is necessary also to be possessed of physical endurance, particularly when flying at high altitudes. It is not proposed to consider in detail here the effects of high altitude flying, beyond pointing out the fact that in such flying all the devices which conduce to efficient respiration and circulation are brought into play. It is on this account that (in the selection and periodic examination of the pilot) particular emphasis is laid upon the stability of the nervous control of respiration and circulation as well as upon general nervous stability. Generally speaking, an adequate opinion of such stability can be formed by the employment of simple tests, but in cases of doubt special measures can be undertaken, as, for example, observations to test the effect of altitude during rebreathing or during rarefaction chamber experiments. Briefly, the signs of such stability may be synopsised as follows:—

(*a*) Steady regular sitting pulse (60–72) rising in rate on standing up by not more than 24 beats per minute and subsiding in a short time to the normal sitting-rate in the very fit, or from 6–12 per minute, or about that rate, in the averagely fit. After exercise (standing on a chair five times 15 seconds) the pulse will increase from the steady standing-rate by not more than 24 beats per minute and will return to the normal standing-rate prior to the exercise in under 30 seconds. Conversely, lack of stability of control and efficiency is denoted by (1) quick pulse (irregular or otherwise); (2) undue immediate increase in rate in standing from sitting; (3) markedly increased standing-rate; (4) undue increase after exercise; and (5) delayed rate of return to normal standing-rate.

(*b*) A systolic pressure of about 120 mm. Hg to 130 mm. Hg with a diastolic pressure of about 75 mm. Hg to 80 mm. Hg, the pulse pressure in the fit being about 40 mm. Hg, and in the averagely fit not more than 50 mm. Hg. Conversely, lack of stability of control and efficiency is characterised by: (1) unduly raised systolic pressure (after all efforts to abolish temporary nervousness have failed); (2) diastolic pressure (*a*) about 95 mm. Hg (suggestive of nervous instability or excessive consumption of alcohol), (*b*) below 70 mm. Hg (indicative of possible predisposition to fainting); and (3) pulse pressures of more than 50 mm. Hg associated with the above conditions.

(*c*) Inability to hold the breath after full inspiration and respiration for about 69 seconds. Below 45 seconds is held to indicate an instability of the respiratory centre and lack of respiratory efficiency which may or may not be associated with disease.

(*d*) Inability to maintain a relatively steady pulse-rate while supporting by blowing a column of mercury with the breath held.

The technique of this test is as follows:—

With the nose clipped, the subject is asked to empty the lungs completely, inhale fully, blow the mercury to the height of 40 mm., and maintain it there without breathing as long as possible, the pulse being counted in periods of five seconds during the performance of the test. The average time in a large number of cases is between 50 and 60 seconds. A time less than 40 seconds is very unsatisfactory. In a good subject the pulse-rate may remain practically unaffected or may rise gradually in rate from 72–96, according to the time the breath is held. The pulse may rise almost at once from 72–84 or 96, and be sustained there. A large rise in rate—e.g., from 72–132 or 144—is unsatisfactory, and is held to be indicative of abdominal venous pooling. In cases of marked physical inefficiency a characteristic response is for the pulse to jump up to a very quick rate—e.g., 132–144—during the second or third period of 5 seconds, and then to fall away in rate to normal or even below normal. Such cardio-motor instability is an adverse factor in aerial work, and is an indication for rest. The test to be recorded thus:—

First, the number of seconds during which the mercury column is sustained, then the normal sitting-rate per five seconds taken before beginning the test, and then the number of pulsations in each five-second period, the time taken to blow the mercury to 40 mm. being ignored. The normal sitting-rate should be separated by a stroke from the first figure of the pulse response during the test—e.g., 50 seconds 6/6, 6, 7, 7, 7, 8, 9, 8, 8, 8, 8.

Blood Pressure.

Observations of the blood pressure during the test confirm the fact that this test elucidates also the stability of control of the blood pressures as well as of the pulse-rate. When performed to an average degree of discomfort there is in the fit subject over a period of 50–60 seconds a rise in the arterial pressure of about 30–40 mm. Hg—e.g., 120 mm. Hg–160 mm. Hg. In the less fit the pressures with attendant pulse acceleration rise more quickly and to a greater height—e.g., 130 to 180 mm. or 190 mm. Hg—generally speaking, 50–60 mm. in about 45–50 seconds. In the unstable the rise is even more marked, and may be as great as 80–100 mm. Hg in a space of 30 seconds—e.g., 160–240 mm. Hg. It is noteworthy that the greater part of such rises in pressure takes place in the first 15 to 20 seconds. This is interpreted as affording information in respect of abdominal pooling. The abdominal effort necessary to sustain the column of mercury increases the intra-abdominal pressure. In subjects with a tendency to abdominal pooling this pressure drives the blood onwards to the right heart, causing thereby an increase of heart-rate, together with an early marked rise in arterial pressure. In subjects where this pooling is unduly great the systolic pressure becomes so increased that, following the acceleration of the heart due to an increased supply of blood to the right side of the heart, there supervenes reflexly through the action of the vagus a slowing of the heart-rate mainly owing to the stimulation of the depressor nerve endings in the aortic arch.

I think it may be safely stated that physical efficiency for flying duties is associated with stability of the centres controlling the respiration and circulation. A falling away of such stability is one of the earliest—perhaps the earliest—sign of deviation from true physical fitness. It is, therefore, a sign of the greatest possible value. It is found alike in those who are out of condition or stale; frequently also in those suffering from mild infections such as a common cold. It is particularly marked in cases of debility following disease, especially in cases of "nervous exhaustion." In many cases of psychoneurosis the stability or otherwise of the lower control centres forms a valuable guide as to the form of treatment best employed for the condition. It has been found that in many cases of psycho-neurosis due to flying stress the primary cause of failure has lain with the lower rather than with the higher centres. In such cases timely rest and exercise at an early stage is all that is required to restore full physical efficiency. Early recognition of the condition forms the essence of successful preventive treatment, since at a later stage prolonged psychotherapy may become necessary. The stability of control of the circulation may also be used as a criterion in subjects who are deemed likely (*a*) to suffer from vertigo in the air due to uneven movement in the air, especially in aerial acrobatics; (*b*) to exhibit a tendency to fainting as altitude increases; (*c*) to be unduly anxious when called upon to perform aerial acrobatics.

In this connexion the following test has been devised:—

The subject is seated in the rotating chair and the nature of the test explained to him. It is pointed out that when a machine is spinning it is relatively out of control. To regain control, it is necessary that the human subject be in a condition to perform certain movements—centralise the controls; if, however, the human subject is out of control, then such movements will not be able to be performed accurately and the machine is likely to continue spinning or to come out of its spin and to go into another in the reverse direction. He will therefore now, while sitting as in a machine, with eyes open and head in best possible position—i.e., looking inside the knee further from the direction of spin—be subjected to a relatively fast spin, 10 times in 20 seconds.

The pulse-rate is noted in five-second periods and arterial pressures are now taken. Immediately after the spin these are again observed and the effects noted. More recently, also, the effect upon the ocular muscle balance has been observed.

In a large number of control tests upon good pilots it has been found that rotation has but little effect, the pulse-rate and blood pressures being only transitorily raised. The following afford three examples of many:—

1. Subject, I. H.; aged $24^{11}/_{12}$. Flying: 1200 hours—all types. General physical condition good. Pulse: sitting, 72; standing, 78–72; exercise, 84; return to normal, 15 seconds. 40 mm. Hg test: 78 seconds = 6/6, 6, 6, 6, 6, 6, 7, 6, 6, 6, 6, 6, 6, 6, 6. On rotation chair—before: pulse, 6, 5, 6, 5; pressures: S., 124; D., 82. On rotation chair—after: pulse, 6, 7, 6, 5, 5, 5; pressures: S., 126; D., 84.

2. Subject, H. N. C. R.; aged $24^{8}/_{12}$. Flying: 1500 hours—scouts and day-bombing machines. General physical condition good. Pulse: sitting, 72; standing, 96–84; exercise, 108; return to normal, 15 seconds. 40 mm. Hg test: 65 seconds = 6/7, 8, 8, 7, 8, 8, 7, 7, 7, 7, 7, 7, 7. On rotation chair—before: pulse, 6; pressures: S., 126; D., 82. On rotation chair—after: pulse, 8, 7, 7, 7, 7, 6; pressures: S., 134; D., 86.

3. Subject, C. T. O.; aged $26^{7}/_{12}$. Flying: 1350 hours—all types. General physical condition good. Pulse: sitting, 72; standing, 84–72; exercise, 96; return to normal, 15 seconds. 40 mm. Hg test: 60 seconds = 6/5, 6, 7, 6, 7, 7, 8, 7, 7, 7, 6, 7. On rotation chair—before: pulse, 6; pressures: S., 122; D., 78. On rotation chair—after: pulse, 6, 6, 6, 6, 6, 6; pressures: S., 124; D., 80.

In contrast may be given the following cases:—

Liability to Vertigo.

1. Subject, R. F.; aged 21. Whenever in air (five times) suffered from nausea, retching, giddiness—especially on descending. On rotation chair—before: pulse, 6; pressures: S., 126; D., 88. On rotation chair—after: pulse, 9, 9, 8, 7, 7, 6; pressures: S., 158; D., 102. Nystagmus time normal.

2. Subject, K. E. S.; aged $24^{10}/_{12}$. Official report: On each occasion that I have taken this officer in the air for the purpose of dual instruction, after about 15 minutes he has collapsed through sickness. Examination 20/6/23. On rotation chair—before: pulse, varying 6–8; pressures: S., 128; D., 82. On rotation chair—after: pulse, 11, 12, 11, 12; pressures: S., 172; D., 98; pulse, 11, 12, not back below 10 in one minute; pressures: S., 170; D., 96. (Two separate observations.) Nystagmus time normal. Ocular muscle balance greatly disturbed.

3. Subject, M. G. R., candidate for piloting duties. History: Train sickness till 6 years of age—does not like swings, &c. General examination: pulse 5½; pressures: S., 134; D., 84. On rotation chair—before: pulse 5½; pressures: S., 156; D., 86. On rotation chair—after: pulse, 10, 9, 9, 7, 7, 6; pressures: S., 182; D., 110. Note marked effects of rotation in addition to anticipatory anxiety rise.

Cases Showing Liability to Fainting.

1. Subject, W. S.; aged $24^{5}/_{12}$. Found permanently unfit flying—1918. On rotation chair—before: pulse, 8; pressures: S., 148; D., 96. On rotation chair—after: pulse, 9, 9, 9, 8, 8, 8; pressures: S., 156; D., 78. Note marked fall of diastolic pressure. This case also shows anxiety, Class III., since pressures taken when not on chair were S., 128, D., 78—which shows the definite anticipatory anxiety rise of pressures.

2. Subject, H. G. History, 1918: After flying 36 hours overseas crashed after a flight of two hours at 19,000 feet—flying full speed into the ground. Has no memory of crash—has not flown since. Examination 18/7/23. On rotation chair—before: pulse, 6; pressures: S., 142; D., 78. On rotation chair—after: pulse, 5, 5, 5, 6, 6, 6; pressures: (1) S., 142; D., 58; (2) S., 140; D., 60. (Two observations.) Note marked fall of diastolic pressure.

3. Subject, M. G., ex-naval officer; candidate for aviation. History: Never liked swings—mother highly strung. Ordinary medical examination: pulse, 72; pressures: S., 134; D., 90. On rotation chair—before: pulse, 6; pressures: S., 146; D., 100. On rotation chair—after: pulse, 6/—87 (imperceptible); pressures: S., 168; D., 70; (after some delay). Candidate fainted for 20 seconds, becoming pale; muscles quite limp. After test, acknowledged that once he had to be carried out unconscious from a swinging tub in Copenhagen.

Anxiety Cases.

1. Subject, R. M. J. Has been suffering from indigestion past two to three months—states feels giddy and faint on ground and in air for last month; suffered from shell-shock during war. At ordinary examination: pulse 72 per minute; pressures: S., 118; D., 76. On rotation chair—before: pulse, 72; pressures: S., 146; D., 74. On rotation chair—after: pulse, 7, 6, 6, 6, 6, 6; pressures: S., 140; D., 76. Note anticipatory anxiety rise.

2. Subject, D. V. A. M.; aged 27. Found unfit as pilot—for nervous symptoms, &c., 1918. General medical examination = unsatisfactory nervous stability and control. Pulse: sitting, 96; standing, 120–108; exercise, 132; return to normal, 25 seconds. Pressures: S., 140; D., 86. 40 mm. Hg test: 40 seconds = 8/9, 10, 11, 10, 11, 10, 10, 10. On rotation chair—before: pulse, 10; pressures: S., 154; D., 80. On rotation chair—after: pulse, 11, 12, 11, 11, 11, 10; pressures: S., 162; D., 72. Note anticipatory anxiety rise in rate of pulse with rise of systolic pressure and fall of diastolic pressure—a result further accentuated in this case by rotation.

3. Subject, D. E. W.; aged $30^{7}/_{12}$. Examined for fitness for piloting duties—has felt uneasy while flying as passenger. "Shell-shock" during Great War. General examination unsatisfactory. Pulse: sitting, 72; standing, 108–96; exercise, 114; return to normal, 45 seconds. Pressures: S., 156; D., 102. On rotation chair—before: pulse, 6; pressures: S., 182; D., 110. On rotation chair—after: pulse, 7, 7, 7, 7, 6, 7; pressures: S., 182; D., 110. Note marked anticipatory rise of arterial pressures, unaffected by rotation.

The main results may be summarised as follows:—

(1) In fit pilots, particularly those accomplished in aerial acrobatics, rotation produces but little effect upon the pulse-rate or arterial pressures.

(2) In cases subject to vertigo, nausea, or vomiting, rotation produces a marked rise in pulse-rate and in systolic and diastolic pressures.

(3) In subjects liable to fainting, rotation produces a characteristic fall in the diastolic pressure.

(4) In highly strung subjects, liable to develop an anxiety neurosis, there is a marked anticipatory rise of pulse-rate and systolic blood pressure prior to rotation, which may or may not be further affected by rotation.

(5) In practice it is found that subjects may tend to exhibit a combination of abnormal responses, but the main criterion is the fact that the satisfactory pilot is relatively stable in his responses.

From the above results, therefore, it will be seen that this test appears to afford valuable information in respect of flying efficiency and can be profitably employed when from the history or general medical examination any doubt is entertained in respect of the likelihood of such efficiency. In regard to the effects of rotation upon ocular muscle balance, these will be dealt with at a later date, in conjunction with Wing-Commander Cecil Clements. It can, however, be stated that results thus far indicate that in subjects who are not incommoded by aerial acrobatics the ocular muscle balance is not affected, whereas in subjects who suffer from giddiness and nausea this is markedly affected. During the general medical examination note is also made of any signs of lack of stable nervous control of circulation, respiration or any other system, since it is considered that stable nervous control in respect of all the bodily processes plays a great part in conferring bodily endurance. Thus undue sweating or signs of vaso-motor disturbance—e.g., flushing—are equally as much as tachycardia signs of instability. So also in certain cases is a heightened body temperature—e.g., 99·2°–99·6° F.—the only ascertainable cause for which is apparently suppressed nervous excitement.

In respect of the alimentary system, any history of alimentary disturbance in the absence of disease must lead to careful investigation owing to the frequency of such abnormal conditions being expressions of disorders of the vegetative nervous system.

Psychic Control.

The degree of higher psychic control over the primitive emotional reactions is assessed mainly by the past history of the subject, and by his demeanour and behaviour under examination. A history of undue emotivity as a child, or of any previous nervous illness, shell-shock or breakdown, is regarded as evidence of unstable higher control with a consequent tendency to break down under the strain of flying duties. The presence of stammer, tics, restlessness under examination is considered to be indicative of such a state. Nail-biting is corroborative of the same. In the clinical examination particular attention must be directed to the state of the deep reflexes and presence or absence of tremors. With regard to the knee-jerk, a brisk response alone is not necessarily considered evidence of instability. Where, however, apart from any question of organic nerve lesion, the limb can be thrown into a state of tonicity by rapid repeated stimuli, a functional inefficiency in respect of higher control is indicated. In some cases the response to the tap of the patellar tendon is a general muscular contraction of more or less the whole body, a valuable sign of defect of the highest centre control, but no indication of the condition of the deep reflexes. Such a response is usually associated with a state of anxiety, conscious or subconscious. Tremor of the fingers is evidence of some disordered functional state, and is often an accompaniment of a general state of heightened nervous excitability. Tremors of the eyelids alone are usually indicative rather of a highly strung disposition or of the result of legitimate stress—e.g., overwork or strain of occupation; tremor of the fingers and hand rather of excessive indulgence in alcohol and tobacco.

Tests for the estimation of the power of coördination of opposing groups of muscles are of considerable value in elucidating the state of higher nervous control. In the "self-balancing test" the subject stands with heels and toes touching, the arms being held at the sides. One knee is then flexed to a right angle and the legs held apart slightly. When he has obtained his balance standing on one leg, he closes the eyes and endeavours to maintain the position steadily for 15 seconds. The degree of coördination is assessed by the amount of movement necessary to maintain balance. This test demonstrates the degree of higher control rather than the condition of muscle sense or vestibular stability. Again the subject may be required to raise to shoulder level from a table a board on which stands a small relatively unstable metal rod (of fixed dimensions) and to replace it upon the table without upsetting the rod. The test should be equally well performed with either hand. Besides bringing out any existing tremor, this test demonstrates the state of muscular coördination. Both the above tests are performed with ease in subjects possessing good higher control and a satisfactory performance of the test has been found in efficient pilots. On the other hand, poor performance has been noted in association with states of exhaustion, flying stress, insomnia, and other neuropathic and psychopathic conditions in an early stage of development. In such conditions also will be found an associated lack of nervous control of the respiration and circulation, and, as already pointed out, in many cases it is the failure of such control which predisposes to the breakdown of the higher centres.

In the assessment of efficiency for flying duties, in the case of a candidate, care has to be taken to differentiate as far as possible between states producing temporary lack of nervous stability and control and those in which such lack is of a more permanent nature.

FÆCAL ENTEROLITH OF THE SMALL INTESTINE.

BY R. J. MORRIS, C.B.E., M.D. DURH., M.R.C.P. LOND.

FÆCAL enterolith of the small intestine is rare. It is the rarest cause of intestinal obstruction, only one case occurring in a 13 years' period at the London Hospital. The diagnosis is difficult, the train of symptoms often extending over a long period, so it is worth while to record the following case in the hope that it may help towards an early diagnosis.

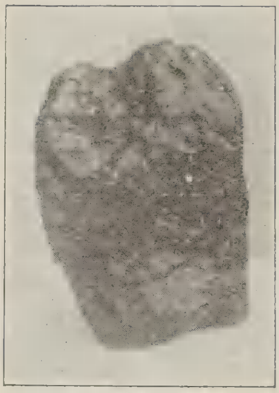
Clinical Record.

Mrs. A. B., aged 68 years, came under my care in July, 1922. She complained of painful and frequent micturition, constipation, alternating with diarrhœa, and spasmodic pains in the abdomen which brought about nausea and vomiting. She gave the following history: Dysentery and fever in India prior to 1880, followed by chronic constipation; acute enteritis in 1894; floating kidney was diagnosed in 1896; operation for fixation of kidney in 1906; and operation for gall-stones in 1907. Many gall-stones were removed, complications followed, and a further operation was performed in 1908. She had partial obstruction of the bowels in 1916, relieved by enemata and other treatment.

Examination of the patient in July, 1922, revealed some irregular bulging on left side of the abdomen, some tenderness over the site of her operation scars, no rise of temperature. Urine was normal. After a short course of treatment she left Harrogate and returned to my care on June 22nd, 1923. She stated that she had had many attacks of spasmodic pain in the abdomen, constipation alternating with diarrhœa, and that for the last three weeks the pains had increased in frequency and intensity. She complained of painful and frequent micturition; urine showed a growth of *B. coli* on culture; pulse and temperature were normal. During the following days the spasmodic pains in the abdomen increased in intensity and peristalsis was visible on inspection. On June 28th she vomited several times, on June 29th intestinal obstruction appeared to be complete. A consultation with a surgeon was arranged, when the conclusion arrived at was that the obstruction was due to malignant disease of the intestine, and operation was decided on. At the operation a hard mass was found lying free in the lower portion of the ileum and successfully removed. She made an uninterrupted recovery, and is now in good health and leading an active life.

In the moist state the enterolith was black and polished, due probably to peristaltic action, nodular on the surface, weighed 33·4 g., 5·5 cm. long, 3·8 cm. in diameter. Section showed no nucleus, texture was spongy, heterogeneous, some parts having a specific gravity greater and some less than 1.

A detailed examination by Prof. H. S. Raper, of the Department of Physiology and Biochemistry, Victoria University, Manchester, is as follows:—



The enterolith.

"The enterolith, when air-dried, was somewhat larger than a walnut and was nodular on the outside. The outer surface was black and shiny. It was much lighter in weight than enteroliths, which are rich in mineral constituents. On section it appeared to be roughly homogeneous in texture, light brown in colour, non-crystalline, and not stratified. It contained 14·0 per cent. of moisture. A portion of the powdered calculus weighing 2 g. was extracted in a Soxhlet apparatus with acetone. The acetone-soluble portion was obtained by distilling off the acetone, and this was extracted several times with light petroleum. The petroleum-soluble substance (fat and cholesterin) was obtained by distilling off the petroleum and weighed 0·146 g. = 7·3 per cent. fat and cholesterin. The portion of the acetone extract, insoluble in petroleum, was very small in amount and consisted of a brown gummy substance.

The residual substance of the enterolith after acetone extraction was now extracted continuously with hot alcohol for four hours. The alcohol extract weighed 0·12 g. and consisted of brownish resinous material from which nothing characteristic could be obtained. The main bulk of the enterolith was insoluble in organic solvents. The weight of the residue left after acetone and alcohol extraction weighed 1·47 g. and represented 73·5 per cent. of the original calculus. It gave protein reactions, a very faint starch reaction with iodine, and contained only a very small amount of ash. Under the microscope it resembled vegetable rather than animal material, and contained many dead bacteria. It was partly soluble in hot dilute sodium hydroxide and in cold concentrated sulphuric acid giving a deep-brown solution. Neither solution showed absorption bands when examined spectroscopically, and since only a minute trace of iron was present, the presence of remains of a blood-clot in the enterolith can be excluded.

To estimate the total protein present, total N was determined in a weighed portion of the acetone and alcohol extracted residue by Kjeldahl's method; 5·67 per cent. nitrogen (=34 per cent. protein) was found. From its appearance and properties it seemed likely that the rest of the extracted residue was mainly vegetable material. To test this, a small portion was treated with cold concentrated H_2SO_4 for two hours. The mixture was then diluted to make the acid 2 per cent. in strength and boiled under a reflux for six hours. The solution was filtered, neutralised exactly with baryta, and allowed to stand. The clear layer above the $BaSO_4$ was siphoned off and concentrated to 35 c.cm. under reduced pressure. The concentrated solution reduced Fehling's solution on boiling and gave a distinct orcinol reaction, indicating the presence of pentoses. It may be presumed, therefore, that the enterolith contained a considerable amount of vegetable matter.

As a result of this examination it appears that the enterolith was principally fæcal in nature, and that it did not originate as a gall-stone, a bile-acid concretion, or a blood-clot. The appearance did not suggest that it was an 'oatmeal stone' such as has been described by Hammarsten (quoted by Cammidge)."

The very careful examination sheds no light on the mode of formation of this enterolith.

Examination by X ray was omitted in this case; had a direct radiogram been taken, the enterolith would have been discovered, because examination by X rays of the section left after analysis cast a very definite shadow, almost as dense as that of bone, and would have shown up clearly in any radiogram taken of the pelvis. It would be desirable in all suspected cases to examine the abdomen and pelvis by X rays, but without the opaque meal, which would flow around the concretion and obliterate it on the radiogram.

A classification by Allbutt and Rolleston[2] includes concretions formed from amorphous fæcal matter. This appears to be the composition of this enterolith, the necessary cause of arrest being the dependent position of the lower end of the ileum, the chronic irritation of the intestine, due to enteritis, providing the colloid menstruum in which the formation took place. Tentative diagnoses of enteroliths have frequently been disproved at operation, but the possibility should be borne in mind. A positive diagnosis in this case would have prevented probably years of suffering and invalidism. A radiograph of an enterolith in situ has been described by Dr. J. Anderson, and this is the only instance I can find in the literature on this subject.

Dr. F. Cowan[16] says that rarely preoperative diagnosis is made, and that little attention has been given to the organic substances which enteroliths contain. Dr. Owen T. Williams[15] says concretions found in the intestine are not fully described, and are usually dismissed as "fæcal concretions," "fæcal accumulation," or "enterolith," often not of a simple nature but as manifestations of some abnormal condition of the intestinal secretion.

Dr. Coerr[5] mentions the fact that most of the enteroliths reported have been discovered at operation or post mortem. The rarity of such should be borne in mind and X rays employed; there are no classical signs and symptoms because of the varying size and position in the alimentary canal. Persistent constipation, digestive disturbances, nausea, vomiting, colicky pains, abdominal soreness, and sensitiveness are the usual complaints.

The concretion may act as a ball-valve causing intermittent obstruction, or becoming wedged may cause complete obstruction necessitating operation. Treves states that the most important symptoms indicative of the presence of an enterolith are persistent attacks of incomplete obstruction of the bowel. A new form of enterolith found in the jejunum in a case operated on for intestinal obstruction is described by Prof. Raper.[17] It is notable that two-thirds of the cases of enteroliths are found in the female.

HOSPITAL EXTENSION AT STOCKTON-ON-TEES.—At a public meeting on Sept. 29th, in response to an appeal for money for the extension of the local hospital, subscriptions amounting to £14,480 were announced, including £10,000 from Sir John Ropner and £1000 each from Sir Frank Brown, Sir John Harrison, and Mr. T. Mellanby. The extension will cost £43,000, of which £31,000 is in hand, consisting of gifts of £10,000 each, with interest, from the late Sir Robert Ropner, Mr. C. W. Littleby, and Mr. Leonard Ropner. This leaves £12,000 to be raised.

ISCHÆMIA CORDIS INTERMITTENS.

WITH NOTES ON THE EXAMINATION AND PROGNOSIS OF DISEASES OF THE HEART AND VESSELS.

By Dr. L. BISCHOFF,
LUGANO, SWITZERLAND.

. . . . and "in difference there is life."—
The late Sir T. Clifford Allbutt *to the author.*

In the following paper I propose to isolate and describe a group of anginoid phenomena, which I would designate as *Ischæmia cordis intermittens* and which I have closely studied. It presents the following peculiarities :—

It affects patients of about from 30 to 70 years, mostly males, who often, after more or less brisk walking (generally in the open) or climbing, or, in fact, soon after any sort of exercise, feel a disagreeable pain behind the sternum, which passes into a feeling of spasmodic contraction and oppressive sensations of anxiety, culminating in such a feeling of annihilation, that the patients are obliged to stop ; and if they must perforce move on can only do so under extreme necessity. It may, indeed, lead to complete loss of consciousness. There is no dyspnœa with this affection. A rest of a few seconds, or at most of minutes, is sufficient to enable the patient to continue his walk in perfect comfort. Soon, however, after the resumption of exercise the pain returns, and rest becomes once more necessary. The history of all patients, with slight variations, reveals the same, almost stereotyped, phenomena.

I will now proceed to mention a few such cases, describing the first a little more in detail.

Case 1.—Railway official, aged 56, sent to me for expert opinion. Nothing special in his history. Three years ago, during an easy walk in hilly country, the patient was suddenly obliged to stop because of an unexpected pain in the chest. After about five minutes' rest he was able to go on. From this time until October, 1922, when a similar sternal pain appeared, lasting somewhat longer, there had been no attack. Twelve days after, as the patient left the house for the first time after a transient abdominal affection, after 50 or 60 steps, the pain returned, obliging him to stop. After two or three minutes he could continue, but again only for 50 or 60 steps, and this recurred five or six times until the end of the walk. Since then these attacks have recurred regularly when walking in the open, but recently the distances walked without pain have become longer (100 to 150 metres). On longer walks the attacks, which in the beginning recurred at short intervals, gradually became rarer, and the distances walked, without pain, longer ; but the pain itself, when felt, is of the same intensity, always obliging the patient to stop. Shortly after food—viz., midday dinner or any other full meal—the attacks are stronger and more frequent. The same occurs when climbing stairs. Apart from these attacks the patient is well. He is a slender, rather undernourished man. Apex-beat felt in the fifth space in the mammillary line, extending down towards the median line and well visible in the epigastrium. This beat is slowly heaving. The heart borders are slightly dilated, both right and left. In the region of the manubrium sterni there is an unusual dullness towards the left. The heart sounds, which are clear and regular, are most easily audible in the epigastrium ; they are heard with difficulty at the bases of the heart. Blood pressure 180–190 max. (variable). Hæmoglobin 70 per cent. Stained blood film shows nothing of note. Traces of albumin in the urine. A screen examination showed a dilatation of the aorta, pulsating synchronously with the systole. In the first oblique diameter there was no filling of the posterior mediastinum ; dilatation of the right auricle ; slightly dilated left ventricle, which is strongly rounded. In view of the dilatation of the aorta a Wassermann test was made but gave a negative result.[1]

After four months the condition of the patient was objectively and subjectively identical. After several genuflexions the pulse was accelerated to 110 per minute ; infrequent suppression (arrhythmia) of a few pulse-waves. Blood pressure: systolic 175, diastolic 110. No pains. Observed in the open (public park), at rest, pulse 64–70 per minute, regular, equable ; blood pressure[2] (conf. Korotkoff) 170–100 ; radialis the same on both sides. After about 100 paces the patient said he felt the pain behind the sternum, radiating to the arms. Continuing the walk he asked to stop after ten paces. Facial expression somewhat anxious. No dyspnœa ; no apocamnosis. Pulse 120 to 124, of alternating form, large and small beats of the oscillometer at (Korotkoff) 190–150 ; strongly alternating murmur pulse and tone pulse with equal pressure of the cuff. Cessation of the pulse (8–10). After one minute's rest improvement of subjective condition. After two minutes the patient continued his walk without difficulty. Pulse 70, regular, equable ; blood pressure 170 (175) –100.

Case 2.—Physician, aged 62. Non-smoker, moderate consumer of alcoholics, good eater, no syphilitic history. Came on account of the above described complaints which had first appeared three years ago. The attacks came on in the open, and chiefly in cold weather. When walking is not at once stopped the pain extends to the left side of the chest, to the left and then to the right arm, and the feeling of oppression on the chest increases and vertigo appears.

State of nutrition good, hypertrophy of the heart, slight dilatation on the left, a ringing second sound of the aorta ; no murmurs. Pulse regular, well, and equally perceptible on both sides (70 per minute). Blood pressure 250–110 (Pachon) ; no albumin in urine (repeated examinations) ; no glucose, no pathological sediment. During an experimental attack the pulse was regular, 100 per minute (same right and left). Blood pressure 260–200. Heart sounds dicrotic.

Case 3.—Painter, sent for report, aged 57, complains of spasmodic painful sensation under the lower sternum and in the epigastric region, which occurs after walking in the open air and obliges him to stop. No dyspnœa. The sensation is accompanied by a peculiar feeling of tiredness in the arms. A spasmodic pain appears also during efforts of defæcation. The symptoms date from two and a half to three years back.

Patient is of plethoric complexion, high diaphragm, emphysematic thorax ; apex of heart in the mammillary line. Auscultation difficult (owing to thickness of panniculus adiposus and extension of lungs) : m.l. (median left), 12·5–13 ; m.r. (median right), 4·5 (orthodiagraphy). Oblique position of heart. Pulse regular, 80–90 ; blood pressure 190–100 (Pachon). After exercise the minimum rises disproportionately (140). Albumin in the urine ; low specific gravity (1004). Hæmoglobin 78 per cent., red corpuscles 4,200,000. Stained blood film nothing of note. Wassermann test negative. The dorsalis pedis and tibialis postica examined on the screen show nothing abnormal. The condition of blood makes chronic lead poisoning improbable.[3]

Case 4.—Female, aged 51, syphilis acquired 20 years ago in South America. For a year past, on walking quickly, she feels compression and pain in the chest. If she does not stop giddiness supervenes. One day, to avoid being run over by an automobile, the patient had to move on when giddiness had already begun ; she fainted and fell, narrowly escaping the car. She was taken home by others. No consumer of either tobacco or alcoholics.

First sound both at base and apex, resonant, with a high timbre as of church bells ; second aortic sound slightly accentuated. Percussion showed no displacement of borders. The near X ray image in the second oblique diameter (position 45) shows a sharply defined bulging and strong pulsation against the aorta "window." Slightly turning the patient to and fro facilitates topography. Pulse 84 ; blood pressure 150–100. Wassermann negative. No albumin in urine ; no glucose. Patient feels oppressed after a short walk in the open air and shows a slowly progressing bradycardia (with regular pulse), and soon giddiness ensues. The walk is not continued.

Case 5.—Civil engineer, aged 53. Family history : The father died of apoplexy. The patient is a strong smoker, partakes of alcoholics in moderation, denies syphilis. On walking in the open he complains of the above-mentioned distress. When walking is continued he loses consciousness and falls. Clonic convulsions of the limbs with foam at the mouth were observed by casual witnesses ; pulse fluttering. After about one hour the pulse is still very rapid. There was no alteration of the heart, either by percussion, auscultation, or orthodiagram. Pulse 74 per minute. In the morning with empty stomach, blood pressure 120 max. ; in the afternoon 160 max., 90 min. Wassermann negative. No albumin in urine, no glucose, no urobilinogen, nothing in sediment. Reflexes slightly increased.

Case 6.—Business man, aged 28, smoker, no syphilis. A month ago, during betrothal, the patient, after walking in the open air, gets the typical pains ; this until the breaking off of the engagement, three days ago. Nothing particular about the heart. Blood pressures 170–95, pulse 80. An experimental walk in the open air has no results. No attack to be provoked even by running.

---

[1] From the report to the chief physician of the Swiss railways, Nov. 27th, 1922.

[2] Brace, manometer, and sphygmometric oscillometer were left in during the whole observation.

[3] From the report to Dr. P. in B.

CASE 7.—I regret being able to report on this case only from memory, as I examined it only as a visitor during consulting hours at the university clinic while I was assistant of Prof. Michaud. The patient was a Russian, aged about 30, rather thin. He smoked much and denied syphilis. Nothing wrong with the heart detected by percussion, auscultation, or fluoroscopy. Pulse normal (?). I witnessed an attack, for after walking about 50 metres rather briskly we were obliged to stop suddenly as the patient felt a strong pain in the manubrium sterni. He became very pale. No dyspnœa. The pulse in the radial was very perceptible. After a stoppage of a few minutes the pallor soon disappeared and the patient could provoke further fits by repeated exertion. The attacks, however, did not occur every day. The patient left for Russia before a more thorough examination could be made.

The intermittent attack after relatively hard exercise, especially in the open air, is common to all these cases. In none of them did the attack occur during rest (in bed), as may happen in true angina pectoris. Dyspnœa was never observed. In the first cases, with general or more local alteration of the vessels, I suppose there is a coronary affection in which the heart is unable to meet greater exertions, and insufficient adaptability (dilatability) of the altered vessels during exercise.

Case 2 might be included in the Bittorf's type of dyspragia cordis, dependent on the advanced age of the patients, with arterio-sclerosis of the coronaries. In Case 4 the patient shows a typical luetic affection of the aorta ascendens. In Cases 5 to 7 the cause of the attacks is probably to be found in an angiospastic neurosis (vasomotor) and an increased vasomotor irritability in the coronary vessels after exercise, something like the benign form of intermittent lameness of the lower extremities through nervous and angiopathic diathesis (Tobias), or through angiospastic diathesis (van Ordt). Perhaps with many patients there is a congenital narrowness of the vessels which Mendel especially emphasises in cases of intermittent claudication. Probably also nicotine comes in here as an exogenous factor, as it often does in intermittent claudication (Erb). I should include in this complex of symptoms some cases published by Mendel[4] of intermittent lameness of the aorta and its branches. In Case 4 the attack would be caused by poor supply of heart muscle through insufficient flow of blood in the coronary arteries (ischæmia) owing to progressively retarded sequence of heart-beats.

We know that epileptic fits (such as in Case 5) occur also in heart-block instead of (or after) the usual fainting fit. The observed tachycardia (Case 5) excludes connexion between these fits and the Stokes-Adams complex. Though observations similar to the above are rightly named "lameness" of the heart, angina pectoris and these special forms are not usually distinguished, so that angina pectoris becomes synonymous with intermittent "lameness" of the heart. Potain already called true angina pectoris intermittent lameness of the heart. Fits of insufficiency accompanied by dyspnœa do not, of course, belong to this present argument, though naturally in case of ischæmia cordis intermittens, with organically altered vessels, the neighbouring aorta ascendens may also be affected (insufficiency and stenosis of the aorta). In the same way other defects of the heart (such as mitral stenosis, &c.) may accompany it (see Gallaverdin).

We thus have to distinguish between angina pectoris vera and this form of disease. Most fits of angina pectoris occur at night or during rest; the above-described features during exercise. Angina pectoris vera has a much more unfavourable prognosis. By taking care of one's self (rest) the fits of ischæmia cordis intermittens do not occur at all—i.e., they do not come when we do not want them to. Angina pectoris vera comes when it will, and may kill in that case. In our cases, as in the usual angina, further prognosis will depend on the ætiology of the ischæmia—i.e., when there are alterations of the vessels, on the extent of such alterations, on the state of the aorta, of the heart muscle and on its reserve power. One can easily see that when there is rigidity and slow response of the vessels, and the heart muscle is then suddenly overtaxed to the point of failure, the prognosis will be a more serious one. A heart with good reserve power will resist better and longer than one without this advantage (lues).[5]

Combinations of angina pectoris with ischæmia cordis intermittens naturally occur, but still only a sharp distinction between limited complexus of symptoms can give us a clear insight into the different forms of disease; hence greater assurance regarding pathogenesis and special prognosis and therapy. The chief requirement is—besides the history which shows the way, and after a thorough clinical examination—to examine the patient during a fit in the open air, that is to walk and climb with him, always closely observing him.

I have named this complex of symptoms *ischæmia cordis intermittens*, as its origin is connected with an insufficient supply of blood to the heart muscle, whether this be due to a pure spasm, insufficient lability of the sclerotic vessels, or other factors, intermittently after exercises like an intermittent lameness of the lower limbs. The qualification, angiosclerotica, angioneurotica might still more define this affection. The statistics, of course, differ according to selection of material in relation to other diseases (intellectual and bodily workers). We know, for instance, that angina pectoris is more frequent among professional men (doctors, lawyers, clergymen, politicians, financiers) than among labourers and peasants, and hence its relative rarity in the hospitals. The fact is also to be noted that while "organic affections" of the heart predominate greatly as causes of death in the black race (½ to 2 times according to Registration Area U.S., 1914–17) angina pectoris does so (2 to 1) in the white race.

EXAMINATION AND PROGNOSIS OF DISEASES OF THE HEART AND VESSELS.

It is very advisable to carry out *auscultation* in a cabinet which shuts out exterior sounds. I much doubt whether it will be possible to register successfully the timbre by instruments. For this the human ear remains the best receiver. The rubber tubes of the stethoscope lower the character of the sounds perceived in proportion to their flexibility and their length; short tubes are, therefore, advisable. It had seemed to me in several cases that the species of the tonality, the timbre (not the intensity) before and after exercise, might inform us as to the efficiency of the heart and vessels, but I can give no definite results. I have never heard a double first sound (during quiet breathing in the entire phase) in cases of ischæmia cordis intermittens, while it has been repeatedly observed in angina pectoris (Huchard), either as "angina de décubitus, produite par le collapsus du ventricule gauche," as Vaquez calls it, or otherwise. I cannot in practice follow the division of Leclerq in classifying angina as A, B, C = cardio-sclereux, aortique, atherome cardio-aortique.

Though the assertion of Mackenzie that *respiratory arrhythmia* can indicate a sound heart cannot be sustained, still it can be accepted as a sign of good compensation. And I would add that the stronger the arrhythmia the better the prognosis (with the same patient). The following example may serve as illustration:—

Mrs. M. C. L., affection of the myocardium with angina pectoris vera, breathing arrhythmia was always present during the compensation of the heart. A few days before the fit the pulse was perfectly rhythmical and strong. During the fit there was tachycardia, but in convalescence the breathing arrhythmia was promptly re-established. Here the arrhythmia was a favourable indication, regular rhythm a bad one. (For causes see Brown-Séquard, Einbrodt, Burdon Sanderson, Hering, Fredericq, Spalitta.)

---

[4] Zentralblatt f. d. ges. Neurologie u. Psychiatrie, xxvii., Nos. 2–3.

[5] In a list of 40 cases of angina pectoris, mostly Parisians, by Martinet, one half had proved luetic affection, which made the prognosis much worse.

In general, and in accordance with what I have set forth, we must suppose that when the heart responds less vigorously to the provocations which vary with the work performed (i.e., if the totality of blood thrown into the system of arteries per minute is invariable), its value as a pump is very probably impaired!

Blood pressure has been measured by the oscillatory method with Pachon's instrument. Though I prefer to use a double cuff (like Gallavardin) for measuring maxima, Pachon's simple cuff was found quite sufficient when measuring blood pressure in the open during trials. Already—as assistant—I had noticed that the blood pressures in the early mornings, with an empty stomach, were often considerably lower than when measured during the day. We know at present that a pressure that varies during the day is more favourable prognostically than a permanently even one, and I would say this is so even when the single peaks of the varying pressure curve reach much higher figures than the moderately high but flatter waves of the other. Only by comparison of pressures of different times of the day can we distinguish between the permanent and the diurnal temporary high pressures. Strictly speaking, the pressure should therefore be measured several times a day, but as this is often unadvisable, either because of an unfavourable psychic impression on the patient or for other reasons, I find two determinations sufficient, that of the early morning as the lower pressure closely approximating the pressure during sleep, and the second determination some time during the late afternoon. It is to be regretted that the observation of pressures during sleep is difficult to obtain. In the purely spastic forms of ischæmia cordis intermittens blood pressure was "variable." The patients with organic alterations showed a lowering of the systolic and at the same time a rise of the diastolic pressure, which, with a strong convergence of the two pressure-curves, gives a bad prognosis.

Radiologically (besides general fluoroscopy) I generally make use of *orthodiagraphy* and mark the pulsations and the excursions of contours. Teleradiograms were of secondary consideration. Special attention was given, firstly, to the aorta, and then to the configuration and range of contractions of the heart under different conditions; of the aorta more especially to the aorta ascendens. As to the aorta, I think that in general much unnecessary importance is given to the so-called "deepened shadow" in cases of sclerosis of aorta ascendens. Apart from the hardness of the tube, the distance of the screen, the stop, &c., which are all technical factors, the personal disposition of the observer at the time plays an important part in the judgment.

Generally, m.r. and m.l. = A.T. of the aorta were measured and its length in comparison to m.r. and m.l. of the heart, for the longer the transversal dimensions of the heart the larger may be those of the aorta without indicating a pathological state of the aorta (always considering the height of the diaphragm and the shape of the thorax, &c.). Hence, absolute single figures (dimensions of the aorta only) may be valueless.

By turning the patient slowly while standing around his vertical axis, one obtains views of the other (chiefly I. and II. oblique) diameters. This slow turning I often find of much assistance in identifying parts of the image. I only have been able to observe one patient fluoroscopically during a fit of ischæmia cordis intermittens. Such observation is rather difficult in itself. Orthodiagrams, in this case of i.c.i., before and during the fit, showed no alteration worth mentioning (f.i. dilatation), but undoubtedly the apparent pulsations and the well visible range of contractions were small. The supposition of a so-called "cramp of the heart"—i.e., of a tonic-spasmodic state of contraction—is completely excluded here. Valsalva's experiment (strong effort of expiration with closed glottis) showed scarcely any (unfavourable) change. Zehl's experiment (expiratory flattenings) did not plainly show any flattening. It is to be regretted that those two experiments are still but rarely made. Indeed, orthodiagraphy as a control is seldom made. While making orthodiagrams I have frequently endeavoured to draw the usual ventricle diastole, and vessel systole orthodiagram (during quiet breathing—as should be made in usual orthodiagraphy), the contours both of the ventricle systole and the aorta diastole. I tried to utilise the observations of varying amplitudes for *determining the functions of the heart vessels*—viz., orthodiagrams taken before and after exercise with indication of the corresponding systole-diastole amplitude. I was very pleased to see that Dietlen supports me in general on this test as a means of forming an opinion on the function of the heart. "By these means one will at least be able to decide in each case if a change in the volume of the heart-beats has occurred."

A complete cinematographic view would, of course, give a still better insight into this matter, but so far this has not successfully been done. Groedel's method, which consists in a combination of a series of radiograms with the corresponding electrocardiograms, might, perhaps, prove useful. But a continuous "film" would give us a far more objective and comprehensible view, with all details and hence with many differentiations (according to each single case). A slowed-down reproduction, such as commonly done in picture theatres for showing gymnastics, diving, &c., would permit an even closer study of details.

The strength and quality of the pulsations at the beginning of lues at the aorta as shown on such a film and compared with the latter observation, would reveal the cicatrisation, if any, which may have been produced by specific treatment (in the form of a reduced pulsation?).

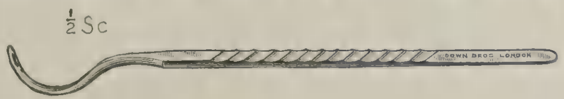
I believe I am the first who has clinically examined in the open air cases of ischæmia cordis intermittens during purposely provoked fits,[6] and I trust I have indicated several new methods and directions for work to be followed in the diagnosis of heart affections, and especially also in their prognosis, which may prove of interest.

The late Sir T. Clifford Allbutt very kindly assisted in translating the technical words into English (1923/24).

New Inventions.

A CONVENIENT DISSECTOR.

IN the operation of transfusion of blood it is desirable that the veins, whether of donor or recipient, should be handled as delicately as possible, and finding that most of the instruments for this purpose were unduly heavy, I have had constructed a combined dissector and aneurysm needle (see figure.). The instrument is made of rustless steel, and is very light. The aneurysm needle is flattened and takes up very little room in the wound. The shaft is serrated and is flattened at its end to an edge which is almost sharp. It is conveniently employed in conjunction with a pair of cilia forceps with very light springs, the points of which are toothed. Both instruments are also useful for fine dissections on experimental animals.



Messrs. Down Bros., Ltd., are the manufacturers.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

THIS Section held its first meeting of the session on Oct. 1st, Mr. T. G. STEVENS, the President, occupying the chair.

Per-uterine Insufflation of Fallopian Tubes for Sterility.

Dr. I. C. RUBIN (New York) read a paper, enriched by numerous epidiascopic illustrations, entitled Diagnostic Value and Therapeutic Application of Per-uterine Insufflation of the Fallopian Tubes in Cases of Sterility. He said the method was devised to determine the patency of the Fallopian tubes, and that before its introduction it was necessary to do exploratory laparotomy in the kind of cases under review. In 1914 he commenced his attempts with collargol, but the results he did not regard as favourable, as patients complained of distension and epigastric distress, and when standing up there was pain in the shoulders and diaphragmatic region. Carbon dioxide was substituted for oxygen, as the former was more rapidly absorbed from the peritoneal cavity. With regard to spasm of the tubes, he soon realised that there were cases in which the first test by insufflation seemed to indicate that the tubes were non-patent, but on a second or a third trial gas was forced through the tubes into the peritoneal cavity, and a fourth repetition showed that the gas could be forced through at a relatively low pressure. In the early cases he was content with ascertaining whether, in a given woman, the Fallopian tubes were open, but it was now possible to ascertain by the method whether one or both tubes were open, and it was not necessary to inject opaque solutions. In cases of normal patency the pressure rose to 40, 60, 80 mm. of mercury, then dropped, then fluctuated for a time, and the patient did not complain of pain. If the pressure rose to 140 or 160 mm. and then dropped, it showed there was a distinct stenosis or obstruction which was remediable.

Contra-indications and Dangers.—The presence of purulent discharges from the cervix, vagina, and urethra constituted a contra-indication to insufflation, as did also the presence of tumour masses in the pelvis, and particularly if tense. Even if there were only tenderness in the pelvis on bi-manual examination, without a palpable tumour, he would not adopt the insufflation method. Those who prescribed the method originally and those who had followed the procedure carefully did not have any trouble from it at all. The cases of trouble were those in which the practitioner attempted it without having fully studied it, and had applied it at an unfavourable part of the menstrual cycle. It should never be practised during the menstrual flow, nor on women who suffered from serious cardio-renal disease. If cases were properly selected, danger from embolism could be practically discounted. The injection should be carried out slowly and carefully. He had not had any peritoneal reaction in 1600 cases. The safest time to insufflate he had found to be four or five days after the cessation of the last regular period. The worst time for it was just prior to a period falling due. A month should elapse before repetition.

Results.—Dr. Rubin said that since he adopted the method he had been seeing among his patients an increasing number of pregnancies. He had studied the effect on the menstrual period and noted that in quite a number there had followed a relief of dysmenorrhœa. In 1000 consecutive cases in his practice there had been 10 per cent. of pregnancies, and these were not ascertained from inquiry instituted, but were voluntarily reported by the women themselves. As a result of a questionnaire sent out there were reported 52 pregnancies out of 763 patients who were treated by the method for sterility. Most of the cases were of women who had been married four or more years, and when 10, 15, or more years of childless married life had been experienced, and then coitus following the insufflation resulted in pregnancy, he thought the claim of cause and effect was a just one.

In describing the mechanism of the procedure, by the aid of slides, Dr. Rubin pointed out the importance of the tube reaching well up beyond the internal os. In some cases a mucus plug, not visible at the external os, as it occupied the deeper portion of the cervical canal, was seen to be expelled after insufflation and when the cannula had been withdrawn. Such removal must, he contended, be a factor in some of the successful cases; and the same applied to the straightening out of tortuous tubes. He believed that in some patients the insufflation had a psychic effect on the patient, curing a spasm which had sufficed to close the uterine ostium.

Discussion.

In the brief discussion, Dr. S. FORSDIKE said he had been using the bulb method for 15 months, and thought the critics of that method had exaggerated the danger of escape of air. His use of the bulb method followed on some researches he conducted on cats with lipiodol, careful examination of the tubes of these cats showing that the use of the method on the human being was fully justified.

Mr. A. W. BOURNE, having used the method, said it would be a great advantage if X rays could be dispensed with as a means of ascertaining whether the gas had passed through the tubes, reliance being placed on hearing with the stethoscope applied to the hypogastrium the noise of the passage of the gas. He questioned whether the rubber acorn on the cannula sufficed, in the case of ulcerated and otherwise irregular cervical surfaces, to prevent leakage.

Dr. T. WATTS EDEN referred to two cases in which he tried the method. In one the patient had had one or two miscarriages and had a retroverted uterus which, he thought, was adherent. She was anxious to have a child, and he thought it would be a good chance to use the method, having the patient under anæsthesia in case an operation was required. There was a rapid rise to 300 mm., which was sustained, and no gas went through. He found the uterus was retroverted and lightly adherent to the pouch of Douglas. There were no tubal adhesions, and he could pass a probe up to the uterus on either side. The second patient had never been pregnant, but wished for a baby. Her uterus was large and hard, but movable, and there was no evidence of pelvic inflammation. According to the instrument there was a block in both tubes, but he found that she only had a small interstitial fibroid in the fundus of the uterus, both tubes being healthy.

Mr. VICTOR BONNEY said his view was that if a woman wanted seriously to have a child the aim should be to remove any structural defect which could be found, and that was one reason why he had not done tubal inflation except under an anæsthetic. If he found a tube was blocked, his practice was to open the abdomen at once. Sterility was commonly associated with retroflexion, and in many cases there was a blockage of the tubes. In some cases V-shaped kinks were found, and these could not in some cases be straightened out as a fine band united the two limbs of the V, and this had first to be divided.

Exhibition of Specimens: Endometrioma.

Mr. BECKWITH WHITEHOUSE (Birmingham) showed an endometrioma which had invaded the bladder of a single girl, aged 22, who had never menstruated. He said there was an element of doubt as to the ætiology of this class of tumour—i.e., as to whether endometriomata were due to regression of the menstrual discharge in the Fallopian tube, or whether they were grafts of endometrium upon the organ or peritoneum upon which they rested. This girl complained of intense pain in the pelvic region, particularly on the right side, at regular four-weekly periods, so severe as to compel a temporary cessation of work. She had never experienced menstruation in the ordinary sense. Examination showed she was virgo intacta, that the uterus was irregular in shape, and the appendix somewhat matted. At operation the uterine appendages were found to be surrounded by adhesions; the tumour was on the anterior wall of the uterus. On opening the tumour there was an escape of the typical tarry material seen in a blood-cyst of the ovary. He therefore opened the bladder, took away a portion of vesical mucous membrane, sutured the bladder, and performed total hysterectomy. The specimen showed a cystic lined cavity, containing this tarry material. The patient made a normal recovery and she was now well and free from pain.

Mr. Whitehouse also showed an intra-ligamentary endometrioma from a married woman aged 33. The patient had been married five years, and in the year previous to attending hospital had had three abortions. At the second abortion she had a retained polypus, and was curetted by the exhibitor, who thought he detected an intra-ligamentary fibroid on the right side. After the third abortion the patient consented to the removal of this fibroid. He found a tumour between the layers of the right broad ligament, and carried out subtotal hysterectomy. On opening the tumour after removal tarry material, as in the last case, exuded. He did not favour the view that these tumours were implantations of endometrium.

Malignant Endometrioma with Lung Metastases.

Dr. A. P. **THOMSON** and Dr. F. W. M. **LAMB** showed a specimen of this description. The former said he was unable to trace a record of anything similar before. He saw the patient, a school teacher aged 27, in 1923, whose menstruation was normal and remained so until the end of her life. In 1923 she started a course of physical training to fit her for a post as games mistress, and after a particular swing race she became very blue and breathless. She returned home under the impression that her heart had been strained. She did her work with increasing difficulty, and in March, 1924, she was sent to Dr. Thomson. She said she had progressively lost weight, the total loss to date being 9 lb.; she also had great lassitude and became short of breath on exertion. There was but slight impairment of the percussion note over the right clavicle, and he heard some fine crepitant râles. There seemed a possibility that she had tuberculosis, and X rays showed a shadowing over the right upper lobe. He therefore sent the patient to Switzerland. When walking there with a medical friend the latter noticed that the patient's face appeared almost black against the snow. She was sent home, and Dr. Morley Fletcher, who saw her, found she had polycythæmia, the blood showing over 6 million reds. Following on repeated distress, Dr. Thomson saw her again in November last, and then the outstanding feature was an intense purplish-black cyanosis. While seated quietly in front of the fire the appearance of the face became almost normal, but the hands were very blue. In the chest there were now only a few fine crepitant râles at the apex of the left lower lobe. She then appeared to have gone to another physician, who told her to take more exercise, and, as a result of attempting to fulfil this instruction, she almost died in the street. A colleague was called and found her sitting in a chair much distressed, and there were crepitations over both lungs. A fortnight later she was seen by Dr. Stanley Barnes, and was still very cyanosed. Shortly afterwards she rallied and entered the hospital under Dr. Barnes. The red cells had then mounted to 12 million, and shortly after the number soared to 13½ million. The dullness on the left side was found afterwards to be due to a left pleural effusion, the fluid being chylous. She continued more or less in this state for six weeks, much oxygen being used to combat the cyanosis, and the red cell count dropped to 6½ million. But she had ascites due to the chylous fluid, and died soon after this started. No satisfactory cause for the illness was ever found. Post mortem a chylous effusion was found on the left side with complete collapse of the left lung. The heart and great vessels were normal. The right lung showed a curious emphysema, and in the abdomen, along the course of the aorta, there were enlarged glands. Apparently the chylous effusion in the abdomen and thorax resulted from direct pressure on the thoracic duct.

Dr. Lamb demonstrated the section of the growth in the recto-genital space, showing that it contained aberrant muscular tissue. No connexion could be found between the tumour and the other part of the pelvic organs. He preferred, for this tumour, the term adenomyoma, as its essential constituent was muscle. The lungs did not show a nodular metastasis, but were very friable, and looked like soft red rubber. A professor in Birmingham suggested that there might be some obstruction to aeration of the blood which did not, however, obstruct the vessels, and that seemed to be the case.

Reviews and Notices of Books.

THE NORMAL MIND.

An Introduction to Mental Hygiene and the Hygiene of School Instruction. By WILLIAM H. BURNHAM, Ph.D., Professor of Pedagogy and School Hygiene in Clark University; Member of the Joint Committee on Health Problems of the National Education Association and the American Medical Association. London and New York: D. Appleton and Co. Pp. 702. 16s.

WRITERS on the subject of mental hygiene and societies directed towards its promotion have been prone in the past to devote most of their attention to the subnormal and the abnormal. In this book, which is designed as an attempt to apply scientific knowledge towards the guidance of the development of mind, and particularly the mind of the school child, Dr. Burnham deliberately concentrates upon the normal, and only incidentally for purposes of illustration deals with departures from the normal, whether failures in development or temperamental inequalities of development. He starts with the fundamental proposition that the essential characteristic of the normal mind is integration of the personality, which implies adjustment to the environment. On the intellectual side of the mind he finds this integration expressing itself in the capacity for concentrated attention, the habit of orderly association; and on the temperamental side in the control of disordered instincts, the solving of mental conflicts, and the removal of harmful repressions. The means by which to attain integration is that of coördinated activity, physical and mental, in the doing of significant tasks. He promulgates three essential conditions of integration and therefore of mental health—the task, which may be anything from the immediate goal of the moment to the more remote ideals of life; the plan, which makes the work purposive; and freedom. These points are discussed with a wealth of detail. He devotes considerable space to the discussion of conditioned reflexes, not merely, however, from a theoretical point of view, but keeping always in view their practical significance in the formation of associations and habits.

Dr. Burnham lays much stress upon the necessity of discovering the superior mentalities and the special directions in which they are superior in order to constitute an ideal social group in which these superior abilities can be integrated for a common purpose. The chief application of intelligence tests in the broadest sense will, he considers, lie in the discovery of the superior individual and his superior talent. Two specially valuable chapters are that on the acquirement in school of right mental attitudes, suitable interests, and proper habits of study and thought, and that on suggestion. Freud's contributions to psychology are sanely applied, and placed in proper perspective. The book, while designed for educationists, is of value to anyone who desires to learn to think clearly and avoid the cultivation of bad mental habits. The medical man who is necessarily nowadays a psychologist will find it eminently practical. To the school doctor it should be of special interest. If the book has a fault, it is in a tendency to prolixity.

A Clinical Handbook of Mental Diseases.

For the use of Students and Medical Practitioners in India. By W. S. JAGOE SHAW, M.D. Belf., M.B., Ch.B., B.A.O., R.U.I., Lieut.-Colonel I.M.S., Superintendent, Central Hospital for Mental Diseases, Yeravda, Poona. Calcutta: Butterworth and Co. (India), Ltd. 1925. Pp. 202 + 29. Rs.3.

THIS interesting and instructive little book is eminently suitable for its purpose. Directed to the assistance of the student and practitioner in India, who no doubt must often be called upon to face the practical problems involved in the treatment of mental disorder, it provides in a comprehensive and compact form just the information he requires to enable him to envisage his difficulties and to see roughly on what lines he may solve them. Naturally, the subject is treated somewhat superficially and contentious matters are avoided, but the author has introduced all that is of practical importance and the book is in every way quite up to date. The appendices which deal with the practical methods of securing the proper accommodation for the treatment in India of both Europeans and Indians, civil and military, and of arranging for the transfer from India to England, are very important. It is in such matters that the patient is most liable to suffer from the lack of experience of the practitioner. The low price of the book should make it accessible to all who may be brought into contact with the mental patient.

Local Anæsthesia.

Die Örtliche Betäubung. Seventh edition. By Prof. Dr. HEINRICH BRAUN. Leipzig: Johann Ambrosius Barth. 1925. Pp. 511. M.22.50.

The Technique of Local Anæsthesia. Third edition. By ARTHUR E. HERTZLER, A.M., M.D. London: Henry Kimpton. 1925. Pp. 272. 25*s.*

THE increasing interest which is taken in local anæsthesia is reflected in the two volumes before us. Both are new and enlarged editions of well-established works and they include many pages devoted to methods not even mentioned in former editions. Prof. Braun deals with the subject with the thoroughness familiar to students of his earlier editions and characteristic of the German mind. Commencing with the great aphorism of Hippocrates "Divinum est opus sedare dolorem" he traces the history of local anæsthesia from the earliest times down to the present day. From the use of compression by Patroklus at the siege of Troy he tells the story of the use of cold by Larréy in the Russian campaigns down to the superb injection methods of modern anæsthesia. It is strange that cocaine, discovered by Pizarro in 1572, should only in 1884 have been used by Kollers for the anæsthesia of the eye. In spite of its dangers cocaine remains pre-eminent as the most powerful anæsthetic we know, but Prof. Braun gives an exhaustive account of the many substitutes which chemical research has placed in our hands, and of which novocaine, until quite recently, has been the most successful.

The surgical methods of anæsthesia are described by Prof. Braun with great elaboration and with a completeness of technical detail which will appeal to all who practise their use. The instruments required are exactly described and beautifully illustrated, and on every page will be found hints invaluable to the practical surgeon. The application of local anæsthesia to the various regions of the body are fully described and superbly illustrated, and include a full discussion of such up-to-date methods as sacral and splanchnic anæsthesia. The volume is replete with original ideas, and the method of anæsthetising the palm from the back of the hand is a surgical manœuvre so neat as to repay the cost of the book. From the illustrations a surgeon, even without a knowledge of German, may learn a vast amount about technique. The book concludes with a list of 2000 references, obviously selected with great care. To the student of German psychology two small points will be of interest. From the text no fewer than 4000 foreign words have been expurgated and the title of the book has been changed from "Lokal-Anästhesie."

Dr. Hertzler's volume makes no pretension to encyclopædic compass, but succeeds in giving a sufficiently full account of the methods of the art. The book is well printed and illustrated, and those who wish for practical information without great elaboration will find it ample for their purpose. There can be no question that local anæsthesia has a great future before it, and surgeons will be grateful to the authors of these two volumes for their assistance in one of the most beautiful of the surgical arts.

Anatomy.

Buchanan's Manual of Anatomy, including Embryology. Fifth edition. Edited by E. BARCLAY-SMITH, M.D., King's College, London; J. E. FRAZER, F.R.C.S., St. Mary's Hospital; F. G. PARSONS, F.R.C.S., St. Thomas's Hospital; and W. WRIGHT, F.R.C.S., London Hospital. London: Baillière, Tindall and Cox. 1925. With 810 illustrations, mostly original and in colours. Pp. 1702. 35*s.*

THE last edition of this popular manual, which appeared six years ago, was produced under the editorship of a committee of anatomists in London, but as it was largely in the nature of a reprint their efforts were subject to considerable restrictions. In the present instance they have had a freer hand, and have revised and in some cases extensively rewritten the text, while adhering in the main to the general arrangement. This is particularly noticeable in the sections dealing with the limbs. Many new and good illustrations have been added. As hitherto, the book deals with anatomy from the regional standpoint, and for this reason is eminently suitable for general reading. The old terminology is adhered to. An excellent index facilitates use as a book of reference.

As regards embryology, the work includes what is practically a new manual on the subject. There is a chapter on general embryology at the beginning of the book, and the more detailed development of the various organs is described under the several headings. The descriptions are sufficiently long to fulfil their purpose and sufficiently short to invite reading, and we feel sure that the student will welcome this section, requiring as he does authoritative, concise, and up-to-date information on this, to him, nebulous branch of anatomy. The practical guide to dissection omitted from the present volume is to be published independently.

We can confidently recommend the new "Buchanan."

Case-taking.

Notes on Medical Case-taking and the Examination of Patients. By G. S. HAYNES, M.D., M.R.C.P., Assistant Physician, Addenbrooke's Hospital. Cambridge: W. Heffer and Sons, Ltd. 1925. Pp. 57. 3*s.*

THIS is a handbook for the use of students in their examination of clinical cases, of a size easily carried in the pocket, interleaved with blank pages for notes. The main systems are set out in reasonable detail, without cumbersome minutiæ, the circulatory system having more space devoted to it than the alimentary, respiratory, and nervous. Curiously enough, the hæmopoietic system has been omitted altogether, while under the nervous system there is no mention of the examination of the pupils. The author has noted the significance of important signs in order to make the manual more lucid to the student. A typical case record is included.

Handbooks of this type are of assistance to the student in forming habits of systematic observation of cases, and this is a good example of the type.

PRACTICAL OPHTHALMOLOGY.

Causeries d'Ophtalmologie Pratique. By Dr. A. CANTONNET, Ophthalmologist to the Paris Hospitals. Paris: A. Maloine et Fils. Pp. 325. Fr.16.

THIS little book, a welcome variety from more formal text-books, contains much useful information, and is sufficiently stamped with the individuality of the author to make it interesting to the advanced student. It is before all things practical, and begins characteristically with a description of how best to examine the eyes of a photophobic child. It is by no means limited to the elements of the subject, however, and we very soon come to a section on examination with the red-free light and another on testing the sight of the aviator. Details of refraction and operative treatment are not dealt with, but the chapters on symptoms and diagnosis contain matter of interest to every surgeon. It is pointed out, for example, that in recent cases of syphilis with headache there may be hypertension of the cerebro-spinal fluid from subacute or chronic serous meningitis, and this may be the cause of choked disc. Another possible cause not generally recognised is traumatism of the skull. In any case of choked disc temporary obscuration of vision should be regarded as a danger-signal calling for serious consideration of an operation for decompression. In some cases of ophthalmia neonatorum no gonococci can be discovered, and it is probable that these cases are caused not by microbes at all but by non-microbic structures which have been found in the conjunctival epithelium of the infant, as well as in the vagina of the mother and the urethra of the father. One cause of those cases of muscular paralysis often ascribed to cold is arterio-sclerosis.

These are samples of the subjects of these lectures, and although the opinions of the author are not invariably orthodox, they are always worthy of consideration. The author has an original mind. In connexion with binocular vision he invented the well-known experiment of the "hole in the hand." In this book there are diagrams which we do not remember to have seen elsewhere, showing the different effects of salt solutions of different concentrations on the cornea. Even in such a subject as the non-operative treatment of glaucoma, a method of administering pilocarpine drops is described which seems well worthy of trial.

EXPERIMENTS IN GENETICS.

By C. C. HURST. Cambridge University Press. 1925. With 175 figures. Pp. 578. 50*s*.

THIS handsome quarto contains the record of 30 years of active work in breeding animals and plants. It consists of reprints of 38 papers and addresses. The first, published in 1897, deals with the curious generic hybrids which can be made in orchids; the last (1925) is an analysis of the chromosome constitution of the species of Rosa throughout the northern hemisphere which ends with a promise of a great deal more on the same subject. The wide field which Dr. Hurst has covered at Burbage in Leicestershire includes also the coat colour of rabbits, fowls and their fecundity, horse-breeding, snapdragons, human eye colour, and other subsidiary subjects of genetical inquiry. The whole forms a record of which anyone might be proud, and it covers a moving period in the history of inheritance, because the early observations were made in pre-mendelian days and the latest in the light of the most modern cytological refinements. It constitutes in this way a sort of running commentary on the progress of the science of genetics, and it is for the most part easily intelligible to those who are not very familiar with the advanced nomenclature of mendelism. We could have wished for one improvement—that the author had made rather more ample commentary on his earlier results in the light of what has transpired since. His notes are few and brief.

TREATMENT.

A Text-book of Practical Therapeutics. Nineteenth edition. By HOBART AMORY HARE, M.D., Professor of Therapeutics, Materia Medica, and Diagnosis in the Jefferson Medical College of Philadelphia. London: Henry Kimpton. 1925. Pp. 1061. 36*s*.

A NEW edition of this book follows quickly on the last; a successful book in medicine and its branches has to come out often, for medicine is changing rapidly. The use of insulin, the internal application of iodine in exophthalmic goitre, the development of the Schick test, variation in drugs used in syphilis, all mark steps of advance. As in previous editions this book, which is really an index of treatment, consists of four parts, all alphabetically arranged—namely, general considerations, drugs, remedial measures other than drugs, diseases. Information may thus be reached from different sides either under the disease or under the remedy; cross references and indexes are full and good, so that everything is easily found. The reader will like the book better the more closely he studies it; it is full of information and eminently readable.

Ghosh's Treatise on Materia Medica and Therapeutics. Tenth edition. By BIRENDRA NATH GHOSH, Examiner in Pharmacology, University of Calcutta. Calcutta: Hilton and Co. 1925. Pp. 718. 10*s*. 6*d*.

THIS edition of Rakhaldas Ghosh's book has been undertaken by B. N. Ghosh alone, as Major-General B. H. Deare has retired. It has now passed through five hands in its ten editions. The present edition does not differ much from the ninth in general form, but several drugs on which recent work has been done have been written up afresh. Some of these, as antimony in leishmaniasis and carbon tetrachloride, are of especial interest to the Indian student. The book is a good, if somewhat heavy, summary of pharmacology and therapeutics culled from the best sources. The editor acknowledges that he has availed himself of the work of Cushny, Clark, Dixon, and Sollmann, than whom there are no better exponents of pharmacology.

TEXT-BOOK OF MEAT HYGIENE.

By RICHARD EDELMANN, Ph.D., Professor at the Royal Veterinary High School, Dresden. Fifth revised edition by JOHN R. MOHLER, A.M., V.M.D., Chief, United States Bureau of Animal Industry; and ADOLPH EICHHORN, D.V.S., Director, Veterinary Department, Lederle Antitoxin Laboratories. With 161 illustrations and 5 coloured plates. London: J. and A. Churchill. 1925. Pp. 478. 25*s*.

THIS text-book has now passed through five editions and would seem, therefore, to be established as a standard work upon the subject. The book may be considered from two points of view—i.e., as a source of scientific information upon animal diseases, and as a practical guide to meat inspection. Its chief value lies in the information given on the anatomy and physiology of the normal animal and on the most important diseases which may affect animals used for human food. There is a detailed account of the distribution of the lymph glands in animals, the peculiarities of meat from different animals is discussed, and the various bacterial diseases and animal parasites are described in detail. The bacteriological examination of meat as a help to diagnosis is too briefly touched upon to give substantial help. The account of putrefactive change on its bacteriological and chemical side is inadequate, and Eber's ammonia test for putrefaction is still described and illustrated, although it is generally recognised as useless, whilst more modern tests are not even mentioned. Chapter XI., which deals with meat poisonings, is the kind of article which was written on the subject a dozen or a score of years ago. It ignores most of the modern work on the subject, and no one reading it would obtain an accurate account of our present knowledge of meat and food poisoning. It is true ptomaines are not brought forward in this connexion, but decomposition changes and poisoning from *B. coli*, proteus species, &c., are mentioned as important causes of meat poisoning. The section on botulism still gives sausages as the most important causes, while all the recent American work on this bacillus and its relationship to canned foods and to animal diseases is ignored. The account of van Ermengem is accepted as the latest and final information upon the subject.

From the administrative point of view the book is of little service to English meat inspectors. Chapter IV. gives an extended account of the regulations governing the meat inspection of the United States Department of Agriculture which is of interest but is not applicable to English conditions. The judgment sections all deal with American practice. The chapter on abattoirs deals solely with Continental and American conditions and is not of much help as regards the slaughter-houses which prevail in this country. A handbook which at the same time provides a scientific and up-to-date account of the physiological appearances and pathological conditions which occur in animals used for food, which is a reliable guide to their detection and also gives simple accurate information as to the judgment which should be exercised in their condemnation or passing for human food is much needed. While Dr. Edelmann's book contains a vast amount of valuable information it cannot be advocated as a satisfactory practical text-book for the meat inspector in this country.

Constitutional Disposition.

Die Konstitutionelle Disposition zu Innere Krankheiten. Third edition. By Dr. Julius Bauer. Berlin: Julius Springer. Pp. 794. $9.60.

A book of 800 large octavo pages, published in so unfavourable a year as 1917, which has reached a third edition, must obviously be meeting a demand, and undoubtedly such a work as this of Dr. Julius Bauer needed to be written. Of recent years the attention of medical workers has been mainly directed to the agents which, entering the body from without, give rise to disease, and to the mechanisms by which the tissues protect themselves with greater or less success; whereas the inherent qualities of his tissues, which render an individual more or less liable than his fellows to this or that malady, have received much less attention. Diathesis which figured so largely in the medicine of our grandfathers is a word seldom heard nowadays, and we are in danger of forgetting that not all of pathology can be studied in the laboratory.

It is time that we should turn our thoughts back again to the study of constitutional tendencies and of the outward signs by which, in some instances, special liabilities may be recognised. Such a study needs to be based upon the knowledge now available of heredity, idiosyncrasy, protein, sensitivity, balance of hormones, and individual and specific chemical peculiarities. It has been the self-imposed task, and certainly no light one, of Dr. Bauer to bring together such information upon these subjects as bears upon disposition to diseases of various kinds. Whilst he admits the truth, at the time when it was pronounced, of the dictum of Germain Say, "La disposition est un mot pour masquer notre ignorance," he holds that the time has come when it is possible to define the share of constitutional tendencies in the pathogenesis of individual maladies.

The amount of information collected between the covers of this book is immense, and he who seeks to obtain knowledge of any special deviation from the standard of which we speak as the "normal" will seldom be disappointed, whether such deviation be one often met with or one which is extremely rare. The earlier chapters, which occupy rather more than 100 pages, treat of the subject of constitutional predisposition in its general aspects. The views of various writers, and the nomenclatures which they adopt, are described and discussed. Signs of degeneracy, structural and functional abnormalities, and such anomalies as persistent infantilism and premature senility, are considered. In a full and interesting chapter the liability of some individuals to, or natural immunity from, particular infective diseases receive due attention. The later chapters deal with the several systems and organs in turn; with the anomalies met with of their form and position, individual variations of their functional capacities, and the bearing of all these factors upon the liability of the patient to be attacked by various maladies, and of particular organs to bear the brunt of the attack.

Obviously the whole subject is very complex, and there is little in common between such factors as shape of thorax and lungs as a predisposing cause of pulmonary tuberculosis and a sensitivity to certain proteins which predisposes to asthma. Thus, under the heading "kidney," to take a single example, we find sections which treat of malpositions and malformations of those organs, of obstruction of urine due to structural anomalies, and of congenital cystic kidney. Amongst functional anomalies are included the so-called renal glycosuria and the several varieties of functional albuminuria. Special liabilities, usually hereditary, to nephritis and granular kidney also receive consideration, as also do ischuria and polyuria, the tendency to form calculi, and liability to urinary disorders of nervous origin. Clearly when treating a theme so vast individual items must often receive but brief consideration; for the benefit of those who desire to look further into particular items an ample bibliography is provided, which covers no less than 140 pages; and there is an adequate index.

Incompatibilities in Prescriptions

Fifth edition. By Edsell A. Ruddiman, Ph.M., M.D. London: Chapman and Hall, Ltd.; New York: John Wiley and Sons. 1925. Pp. 330. 12*s.* 6*d.*

The first hundred pages of this book present the common incompatibilities in concise form, the substances treated being arranged in the alphabetical order of their Latin names. This section should be of real value to the busy prescriber. The next section (of about 50 pages) is intended more for the student of pharmacy; it contains a list of 480 prescriptions as an exercise, so that he may study them and find out for himself where the fault is to be found in each one, and the best means of avoiding it. Then follows another long section containing clear and detailed criticism of these prescriptions by means of which the student may check such conclusions as he may have been able to draw. The last section contains a useful table showing the effect of rubbing together equal weights of two solids, and a series of tables showing the solubilities of all the commoner drugs in water, alcohol, ether, chloroform, and glycerine, together with a column showing the solubility of some of the drugs in miscellaneous solvents. A serious blemish in this table of solubilities is the absence of any explicit statement as to the meaning of the figures, the reader being left to deduce the fact that they refer to parts of solvent to one part of dissolved substance. No temperature is indicated; presumably that vague idea, "room temperature," is implied.

The book concludes with two good indexes: one of incompatibilities, the other of prescriptions. It is well printed, and should be a useful desk companion to prescribers and students in this country. It could, we think, be improved by the inclusion of a short introductory section dealing with the general principles of incompatibility.

Mr. Henry Kimpton is the English publisher of C. E. Turner's "Personal and Community Health," reviewed on p. 702 of our last issue. The price is 12*s.* 6*d.*

THE LANCET.

LONDON: SATURDAY, OCTOBER 10, 1925.

POST-GRADUATE EDUCATION.

IN a foreword to the first number of the *Post-Graduate Medical Journal* Sir WILLIAM HALE-WHITE compares the newly qualified doctor to a mariner setting out on a voyage over changing seas. For a time he is well served by the charts which his teachers have given him, but as he finds that the best of charts provided by others cannot meet the developments or emergencies with which he is confronted, he begins, consciously or unconsciously, to make charts for himself. And as the years pass he finds that he requires help in dealing with the new currents; truer soundings have made old observations obsolete, while fresh waters are opened which were uncharted in his pupillage. To provide opportunities for such revision is to raise the standard of medical work, and to meet this need alone justifies the establishment of post-graduate education in this country. The great mass of medical practice must be carried on by individuals largely upon their own responsibility, and it is a function very appropriately performed by the great London hospitals when they offer to their qualified men fresh inspiration in aims, methods, and ideals.

That such an offer evokes an enthusiastic response is shown by the success of the course of lectures given during last week-end at St. Mary's Hospital; an account of the proceedings will be found in another column, and similar developments in this direction at other centres are inevitable. The constituency to be assisted is ready to the hand, and on one side the material from which to draw the necessary teaching is present in superabundance. But while—if the simile is not being too much laboured—the general mariners may be expected to increase in number, and while the object-lessons are aggregated in miserable wealth in the metropolis, we are apt to forget that the pilots are in a most difficult position. Just as to get an accurate knowledge of special seas, and to train for an extra-master's certificate is not easy, except as the result of long preparation, so special teaching in medicine is not a fortuitous accomplishment. Further, many who possess the necessary qualities and gifts may not be available for their distribution; and the arrangements for the work are in London ill-organised because of the vast size of the metropolis, and, at bottom, because of the absence of a great clinical centre. The sound work of the Fellowship of Medicine can be estimated now that that body is issuing regularly a journal, which will be published monthly under the editorship of Dr. ADOLPHE ABRAHAMS. For many years the Fellowship has done its best to remedy the defaults in London for post-graduate education, and has placed at the disposal of graduates a fine assortment of sound teaching, for English teachers are as good and as enthusiastic, given the appropriate milieu, as any European professors. But our great hospitals have a routine for the training of their undergraduate students which assorts ill with post-graduate lecturing and demonstration, and all the experience of those who have thought long and worked hard at the subject points to the institution of a great clinical centre. Meantime the Fellowship of Medicine will continue its useful ministrations. As we are reminded in its new organ, the Minister of Health has appointed a committee, with this reference: To draw up a practicable scheme of post-graduate medical education centred in London. The Committee is strongly constituted and has the situation left by the Athlone Committee in May, 1921, to deal with. The Athlone Committee recommended that a school attached to a hospital centrally situated in London should be devoted solely to post-graduate medical education, a school of the University of London being suggested. A meeting was summoned early in this year by the Fellowship of Medicine, at which free expression of opinion on the existing arrangements for post-graduate teaching was invited, when representatives of the Military and Naval Services expressed satisfaction with the arrangements made for their medical officers; but the conditions in the Services are special, and too much stress must not be laid upon success along this line, gratifying though it is.

A second foreword to the *Post-Graduate Medical Journal* is supplied by Sir BERKELEY MOYNIHAN, who deplores the readiness with which the practitioner—only too naturally—is content to practise on the medicine learned in student days, not realising the joy of dwelling in a land of advancing frontiers. He urges the necessity for practitioners, despite the over busy day to which he pays tribute, to find short periods for reading, as well as leisure to attend meetings of a medical society and the instructions of a post-graduate class, adding with regard to the last the wise comment that discussion and controversy are of the very spirit of scholarship and that comradeship with those who labour transforms competitors into colleagues. The great thing on which all are agreed, then, is that there should be opportunities for practitioners to keep abreast of recent knowledge by contact with those who have the ability and the willingness to teach. And in order to meet this great need of "keeping in touch" the inevitable conclusion is reached that in London, and, indeed, in other large cities, there should be a medical school for post-graduate workers. As far as London is concerned, the cost of providing such a centre, with lecture halls, laboratories, and perhaps a hostel where post-graduates could lodge, has caused the scheme perpetually to be set aside, but it is becoming more and more obvious that only by the foundation of a real post-graduate institute can London take up its right place as the centre of medical teaching not only for the metropolis but for the Empire, attracting also the keenest minds among foreigners. The ideal should be ever present.

◆

THE SOCIAL HYGIENE CONGRESS.

SOON after the outbreak of war in 1914 the Eugenics Education Society addressed a request to the Royal Medical Colleges to support a movement for national education on the subject of venereal diseases. The time was opportune; the Royal Commission on Venereal Disease had just brought in a report making clear for the first time the great prevalence of venereal disease and the inadequacy of the provision for its treatment, especially in London. The segregation in camps of large numbers of sexually active men made immediate action desirable, and a National Council was formed, which held its inaugural meeting on Nov. 11th, 1914, when the aims and objects, as set out, may be summed up as follows:—

To provide public information and medical education, to organise early treatment, and to promote legislative reforms. A strong executive committee was constituted with Dr. Douglas White and Mrs. Gotto as honorary secretaries.

Eleven momentous years have elapsed since this beginning was made, and this week we report the second Imperial Social Hygiene Congress which is the culmination of the work of the National Council. It is difficult for those without long memories to picture the change of fact and heart which have occurred during those 11 years. It was not an impossible thing at that time for a medical student in his clinical years not to know the meaning of venereal disease. The Secretary of State for the Colonies reminded the Congress that in 1911 he found it all but impossible to get a single Member of Parliament to say a word on the subject of venereal disease, and the conspiracy of silence continued almost unbroken until the National Council began its work. Facilities for treatment would be idle unless the public knew what venereal disease is and where these facilities were to be obtained, but enlightenment has been so complete that during the year 1924 over 1,500,000 attendances were made at treatment centres in England and 81,806 attendances in Wales. During little more than a decade the treatment of venereal disease, previously limited to a tiny group of "lock" hospitals and the casual care of general out-patient clinics, was replaced by expert treatment under conditions of entire confidence and secrecy at 184 centres in England and 10 centres in Wales. At several centres in London continuous out-patient venereal clinics are held daily, and a similar centre for women only was recently opened at the Royal Free Hospital; auxiliary clinics for the treatment of mothers and infants are under consideration at the present time in Wales. The effect of all this on the incidence of disease is now beginning to make itself felt, for comparing 1924 with 1920 the number of new cases of syphilis has fallen by nearly 50 per cent., and new cases of gonorrhœa by 23 per cent. Legislative action in this country has not taken any stringent forms. The Venereal Diseases Act, passed in 1917, was little in advance of the public opinion of the day or of the habits of the people, and the only subsequent legislative Act in this country has been the useful little measure providing gratuitous treatment for the mariner at various ports of call. During this time, however, some of the self-governing Dominions have passed legislation making notification a statutory duty on the medical practitioner and even enjoining patients themselves to report within a specified time in face of severe penalty. These measures, as Mr. C. M. Kohan pointed out at the Congress, have, as yet, proved little more than pious aspirations. Queensland, the pioneer of compulsory measures, continues satisfied with their administrative aspect, while regretting the unwillingness of its medical men to fall in completely with the obligation laid upon them. In this country we have remained content with the secrecy of the clinics, hoping thereby to secure the efficient treatment of many who otherwise would be unwilling to attend. Unfortunately, in the last recorded year 40 per cent. of the total cases ceased to attend before treatment was complete, although many of them are believed to have been rendered non-infective before ceasing their attendance. More successful following-up measures have been instituted in certain places, especially Edinburgh.

While all this registers tremendous progress, on which it is well to insist afresh, the situation with regard to the volume of venereal disease is one which must continue to command the attention of the British Social Hygiene Council for many years ahead. Present incidence of congenital syphilis is described by Colonel L. W. Harrison as a reproach, when the disease is a horror which can be completely prevented. The returns for 1924 showed 2532 cases of venereal disease in England under the age of 7 years, 1826 of these being congenital syphilis, the balance largely being those who acquired venereal disease apart from sexual misconduct. In the Navy, for the latest year in which complete figures are yet available, there were, for every 1000 men 113 entries for venereal disease during that year, and the average daily number of sick men was 892. In spite of a recent decline the rate of venereal disease in the Army in 1922 was still 25·9 per 1000, and Major E. C. Lambkin felt it incumbent upon him to assure the Congress that the Army did not condone or encourage sexual irregularity. As a matter of fact 20 per cent. of soldiers became infected while absent on leave; and special difficulties are contended with abroad, particularly in Turkey and on the Rhine—for in Cologne alone there are reputed to be 6000 prostitutes. Similarly, the risk of China and Cape Town to the sailor is very imminent. These figures are sufficiently alarming and indicate that the problems, especially abroad, are not by any means within sight of solution. Ignorance, indifference, and fatalism in the colonies take the place of the despairing public outlook and the deliberate concealment which constitute the chief difficulties at home. Mr. Amery indicated the existence of a Committee of Civil Research, corresponding on the civil side to the Committee of Imperial Defence, which was concerned for the security of national life. The Congress provided opportunity for exchange of information in regard to venereal disease over a very wide area, which may well be considered by this Committee. In Fiji, Dr. P. T. Harper expects syphilis to appear amongst the Fijians in proportion as the ritual inoculation with yaws declines. In Nyasaland, where the problem seems to be primarily political. Dr. G. M. Sanderson aims at training up a native medical profession to spread enlightenment in the villages. In Palestine Dr. J. W. Harkness regards the mild endemic syphilis of the rural population as the result of social rather than sexual intercourse. Amongst such people education must be by word of mouth and is a slow and laborious process; pictorial illustration is hard to devise; to the unimaginative native an enlarged culex on the screen may be indistinguishable from a camel. In India, where Sir Leonard Rogers regards early marriage as a safeguard, and where the Central Provinces are still relatively free from disease, Major-General A. Hooton can see little prospect of progress until more efficient instruction is offered at the medical colleges and schools. A moving picture was drawn by Dr. Kathleen Vaughan of venereal disease in Kashmir, where there is no teaching of any kind on the subject for boys and girls except that given in the few mission schools. The British Social Hygiene Council has in prospect a campaign of social service which will embrace the education in hygienic living, a serious attempt to prevent disease by improving environment, and a review of all aspects of the problem in the Empire.

◆

THE MEDICAL ASPECT OF INDUSTRY.

In his presidential address to the Brighton and Sussex Medico-Chirurgical Society on Oct. 1st Mr. H. J. Walker dealt with the work of the factory surgeon as an important branch of preventive medicine, and one likely to receive attention in the present Parliament. After reviewing industrial conditions in the early nineteenth century and the revolution already brought about by factory legislation, he commented on the fact that even in the present year 37 cases of lead poisoning and six of anthrax were reported to the Home Office, in addition to seven other cases of lead poisoning amongst house painters and plumbers, and he went on to remark on the possibility of eliminating altogether industrial injury from such things as lead, mercury, arsenic, phosphorus, or anthrax. Turning to the larger aspect of industrial problems, Mr. Walker quoted with approval the statement that industrial medicine, if properly applied, might effect a saving of many millions a year in sickness benefit. At present it is only in a few dangerous trades that medical inspection is compulsory. Little objection, he thought, would be taken by the workman to medical examination, provided he thoroughly understood it was for his own benefit. Men continued to work, when unfit to do so, day after day for fear of losing their employment, and there was no doubt that they lost more than they gained in the long run. "Some time back," said Mr. Walker, "I was called to see a man who was found dead in a railway carriage. He was employed in the building line and had been seen running to catch his early morning train. On post-mortem I found a large calculus in one of the valves of his heart. I was informed by his wife that the man had not consulted a doctor for many years and had never complained of any trouble. In another case a man knocked his shin whilst at his work and sought no medical advice until he was incapacitated from work, when on examination the leg was found to be acutely septic. Osteitis of the tibia had developed, necessitating an operation with a prolonged stay in hospital, and a final appeal to the law courts for compensation." He often saw cases of dermatitis and eczematous ulceration of hands and forearms caused by irritation from flour, sugar, mercury, fur preparations or various solutions used in factories. When these cases came for disablement certificates, in order to obtain compensation, the disease in most cases was far advanced, the man having continued his employment until the irritation and annoyance had become almost unendurable. The Factory Bill now before Parliament suggests that young persons up to the age of 18 should be medically examined before starting work. After that age they are supposed to be capable of looking after themselves. Of this, Mr. Walker is very doubtful. "Under the present economical system," he said, "the exigencies of work prevent proper attention being given to health. I would suggest that in all factories and workshops young persons, up to the age of 18, should be examined every six months, a health register being kept with full particulars of the work. If not suitable, and the employer and the employee wish to continue with the same work, the latter should be examined again in six months. If the work is then found to be deleterious to the employee's health, the medical attendant should have power to suspend him from that work. All employees should be compelled to seek medical advice for all injuries and diseases of more than a week's duration, and should not be allowed to return to work without a medical certificate of fitness. Examinations should be compulsory every six months in trades which have a tendency to undermine the employee's health." Mr. Walker admits that there must be individual hardships, but contends that the gain to the community at large would far exceed any hardship to the individual. The expense incurred would be compensated for by filling factories and workshops with healthy and willing workers. More unrest, Mr. Walker thinks, is caused in the industrial world by poor health and uncongenial surroundings than from low wages and all other reasons combined.

BRITISH DENTAL HOSPITAL.—The annual general meeting will be held at the rooms of the British Dental Association, 23, Russell-square, London, W.C., on Thursday, Oct. 15th, at 8 P.M., when Dr. James Wheatley, county medical officer of health and school medical officer, Salop, will give an address on Dental Propaganda. Sir Harry Baldwin, the President, will preside.

Annotations.

"Ne quid nimis."

THE CARE OF THE PRIMIGRAVIDA.

A CORRESPONDENT has suggested that it should be made obligatory for every woman in her first labour to be attended by a registered medical practitioner. The question is important and difficult to answer off-hand. Undoubtedly, at the present time certified midwives conduct a large proportion of first labours without medical assistance, for the most part with complete success. Our correspondent maintains, however, that the first labour is liable to certain complications, which require the wider knowledge and greater skill of the qualified practitioner to recognise and deal with them in time to prevent undesirable results. The practice of the metropolitan hospitals indicates to a certain extent the attitude of the best obstetrical authorities. If they do not recognise any necessity for distinguishing between the primipara and the multipara, it is probable that the present safeguards that surround the practice of midwifery are adequate. The district maternity work of a London hospital is conducted by medical students, from whom different hospitals demand a different standard of qualification. We have inquired of several London hospitals what these standards are. One demands an attendance at five cases before the student conducts an outside confinement; one, under a new regulation, exacts a month's experience; while all others which have a lying-in ward demand a certain amount of inside training. In all except one hospital a qualified obstetrician accompanies the student on his first one or two district cases. A medical student who has completed his clerkship and dressership should have a wider outlook than the midwife, but his brief experience of the labour ward will not make him her equal in her own specialty of obstetrics. If, therefore, the student is considered sufficiently qualified after this training to attend all classes of confinements, it would appear that a midwife who has taken her C.M.B. diploma can quite well be trusted with first labours under the existing legal safeguards. It is interesting to note that none of the hospitals who have favoured us with their opinions make any distinction in practice between primiparæ and others. Nearly all these hospitals, however, attach great importance to the work of the antenatal clinics that they maintain. All women who desire to be attended from the hospital for their confinement are seen at the antenatal clinic early in their pregnancy for a thorough examination, and are examined again towards the end of their time, so that any abnormality that might interfere with labour can be properly treated and its evil results anticipated. Unfortunately, however, only a very small number, comparatively, of expectant mothers in the country come under antenatal examination, and the distinction between primiparæ and others, which London hospitals disregard, may have to be considered among women who undergo their confinements in their own homes. But antenatal work at welfare clinics is slowly but surely making itself felt. A report,[1] which has just reached us, is based on replies received from 500 out of the 641 antenatal centres so far established. These indicate that vigorous work is being carried on in the great majority of areas covered. In 61 per cent. of the centres the medical officer in charge of the clinic has the status or the experience of an obstetric specialist, while most of the remaining 39 per cent. are, or have been, in general practice with large numbers of midwifery cases. An interesting point raised was as to the practice at the various centres with regard to vaginal examination. In only 18 per cent. of clinics was this examination made as a routine procedure, 69 per cent. making it only where considered advisable. This group may increase as experience in antenatal work grows. In the light of available evidence we hardly think that alteration in the existing law would be justified.

SOME LITERARY DEATH-BEDS.

STRESS of life counts high in the literary world to-day. Nevertheless litterateurs of the nineteenth century died, as a rule, at an earlier age than they do now, and they seem to have died of curious ailments. This is apparent from the perusal of Mr. Stewart Ellis's "Mainly Victorian," a collection of essays and biographical notices recently published. The author deals with 30 or more distinguished authors and others connected with English literature whose busy, but often not exceptional, lives ended prematurely during the nineteenth century. Charles Lamb, with some of whose hitherto unpublished letters the volume opens, died, if not at too early an age, then at least out of due season. At the age of 60 he stumbled and slightly injured his face. This brought on erysipelas, which proved fatal. Latterly he had been a hard drinker, but his life had been one of steady indoor work with no particular excitement or excess. Ann Radcliffe, a popular writer of terrifying stories, died at the age of 59, the cause of death not being stated, though her state at the last was one of extreme weakness, and her last words were the comfortable phrase, "There is some substance in that," in allusion to some nourishment administered to her at midnight. Richard Harris Barham, a convivial Church dignitary, author of the famous "Ingoldsby Legends," died prematurely. In 1844 a severe chill brought on violent inflammation of the throat, from which he continually rallied only to become weaker. He was moved restlessly from place to place in search of health, and his old bizarre humour flashed forth for the last time with the remark, as he was carried into his London house, "that he was indeed at Amen Corner." Mr. Ellis then describes the death-bed scene, "when a man of but 56 years of age, and with his brilliant mental powers at their zenith, calmly faced with the bravest fortitude the most appalling experience of humanity." Sorrow at the loss of children and friends may have contributed to early collapse in the sensitive merry writer, but that is not enough to account for a typical nineteenth century death, at once premature and caused by seemingly remediable conditions. Captain Marryat died of cerebral hæmorrhage at the age of 56 in 1847. He also was carried about from place to place in search of a better climate, as though that would assist him. At the last he was kept alive on lemonade, dying in stupor. He had been an intrepid and hard-working naval commander, one who consistently burnt the candle at both ends. He wrote against time, and neglected an old tendency to rupture of blood-vessels. His feverish literary career gives the lie to the assumed placidity and uneventfulness of the 'forties and 'fifties. Thackeray died at the age of 52, after foreseeing his end for a long time. Surtees, the creator of "Jorrocks," died of angina pectoris at the age of 61. He had apparently had no warning of this. Whyte Melville was killed in the hunting field at the age of 57, and he does not therefore come within our purview, but Frank Smedley, author of "Frank Fairleigh" and other stirring romances, was a typical invalid author, who made up to himself for his limitations in the matter of health by the vividness of the adventures he described. In this he resembled R. L. Stevenson, the consumptive creator of "Treasure Island." Smedley was laid up from early youth by an affection of a paralytic nature, which gradually deprived him of the use of his legs and brought on what was then diagnosed as "irritation of the brain." He wrote against his doctor's orders, overworked, and died at the age of 45, passing at the last through a series of epileptic fits. G. P. R. James died a complete wreck, mental and physical, at the age of 59. At the same age died Sheridan Le Fanu. The death of Charles Dickens was self-induced, for he insisted on giving his recitations long after he had been warned against every kind of activity. His medical attendant and friend, Carr Beard, could only sit by and report on the degrees of excitement reached by the ultra-dramatic reciter.

TREATMENT OF INTERSTITIAL KERATITIS.

UP till now there are few ophthalmologists who have displayed any enthusiasm for the treatment of interstial keratitis by salvarsan or its allied compounds. According to most of the prevailing authorities, anti-syphilitic treatment has very little effect. "Unfortunately," says Fuchs, "we must say that in many cases, parenchymatous keratitis, even under the most careful treatment, runs a course that is not essentially different from what would have been the case without any treatment at all." Foster Moore records his conviction that neither mercury nor any of the salvarsan compounds will prevent the onset of interstitial keratitis or the other eye symptoms of congenital syphilis; it is hardly to be expected, then, he says, that they will bring about a cure when the disease is established.[1] On the other hand, de Schweinitz believes that treatment by the salvarsan compounds is most valuable. "Although it does not materially hasten the absorption of the corneal deposits it definitely shortens the duration of the disease."[2] This more hopeful opinion has recently received support from Mr. R. Lindsay Rea, who claims that the end-results of cases treated with injections of novarsenobillon are very decidedly better than if not so treated.[3]

A systematic investigation of the question has been undertaken by Dr. Maud Carvill and Dr. George S. Derby at the Massachusetts Eye and Ear Infirmary.[4] Previous to 1910 the general treatment of interstitial keratitis was carried out at this institution in a more or less desultory fashion. Since 1910 anti-syphilitic treatment has been systematically carried out for all these patients—viz., numerous injections of arsphenamin or allied preparations, mercurials by injection, inunction, and by the mouth, in addition to iodides when indicated. For purposes of comparison 100 of the "untreated" cases were collected and 100 of the "treated" cases and the results tabulated. In the case of the former group the average period that had elapsed since the cessation of acute symptoms was nine and three-quarter years. In the case of the latter, two and three-quarter years. Except for the shorter period of observation of these "treated" cases the comparison seems a fair one. The result is decidedly in favour of treatment. At the most recent examination vision of 20/30 or better was found in 58 per cent. of the treated cases, and in only 28 per cent. of the untreated. In the treated cases only 15 out of 178 eyes had a vision of less than 20/100. One eye had only perception of light. In the untreated, 45 eyes out of 179 had a vision of less than 20/100. Five eyes had light perception only, and in five vision was nil. In spite of the possible fallacy involved in the different period of observation in the two groups these figures cannot be ignored. Another comparison of the number of cases in which recurrences occurred is even more striking, as in this the difference in period of observation was eliminated. In the untreated cases during the first three years recurrences took place in 24 eyes (13 per cent.), as compared with 3·6 per cent. among the treated cases. In the light of these recent observations on both sides of the Atlantic it seems desirable that ophthalmic surgeons should turn their attention to this subject which is of considerable importance. The incidence of the disease is about 0·5 per cent. of the total number of patients at most ophthalmic hospitals, and children blind from it are by no means unknown in the blind schools.

APT PATIENTS.

OUR Vienna correspondent informs us of an interesting experiment that has been carried out at Prof. Pirquet's Children's Clinic in that city. When insulin was discovered some three years ago Prof. Pirquet began the treatment of 30 diabetic children by this means, the cost of which was met by grants from the union of the Vienna "sick clubs" (*Krankenkassen*). Insulin at that time was very expensive, and, in addition to the actual cost of the drug, the unfortunate sufferers appeared doomed to pay medical fees throughout their lives for the minor operation of having the medicament injected subcutaneously. Prof. Pirquet, therefore, attempted the daring innovation of teaching these children to inject themselves. A regular course of instruction was instituted, and the children were taught the principles of sterilisation, how to handle a syringe, how to make an injection, and further, they learned the dietetic values of the various foods suitable for their condition. The older children were taught how to cook their own food. Later on the course was extended to include the relations of diebetic children, and full instruction was given on all points relating to the treatment of the disease, including urine tests. The experiment proved successful, and in a short time it was possible to allow all the children to return to their homes, with the exception of a few serious cases. The children are examined medically every few weeks for control of weight and urine, otherwise they are free from the shadow of hospitalisation. A similar experiment is now being made with cases of myxœdema. This experiment, apart from the happy results it has achieved in individual cases, is of importance in showing how the hospital can be used as a teaching centre for patients as well as students.

THE ERECT POSTURE AND ITS DRAWBACKS.

WHEN by standing upright on our feet we gained our predominance over animals which crouch or crawl, we brought on ourselves by way of payment a host of troubles of which we seem to have reached only the beginning. Dr. René Lambolez, in a recent article in a French medical journal,[1] has described some of them, and as a mathematician has gone very deeply into the dynamics of the erect position, far more deeply than most readers will follow. In addition to those handicaps of abdominal and circulatory trouble that are familiar results of bipedal progress, he deals with curvature of the spine and malformation of the hips, discussing especially scoliosis. Monod wrote in a thesis in 1909 that "it is not the exigencies of study that make a scoliotic, but the fact that [the child] attends school during the years when he is exceptionally liable to scoliosis," and Dr. Lambolez points out that if there is a tendency to deformity in a child, prolonged and constantly repeated harmful attitudes will produce it. The especial importance of the vertical position is in those scolioses that result from asymmetry of the fifth lumbar vertebra, or the so-called "static" forms that are due to an inequality in the length of the legs, malformed hip, or a unilateral flat-foot. The term covers, of course, a vast number of malformations due to different causes, and their treatment can be neither exclusively medical nor exclusively orthopædic. True scoliosis of bony origin benefits immensely in its early stages from rest in a recumbent position; later on the deviation from the vertical may have to be compensated by appliances. Pott's disease, before deformity appears and while it is still in the stage of functional impotence, is also best treated by complete rest and relieving the vertebræ from the strain of the upright position. Dr. Lambolez quotes Prof. Calot as authority for his statement that minor malformations of the hip-joint are at the bottom of half the ailments wrongly diagnosed as coxalgia, three-quarters of those diagnosed as tuberculosis of the neck, and nine-tenths of those that pass as localised rheumatism or dry arthritis, and he also maintains that all the coxa plana cases observed by Waldenstrom and all the "osteochondritis" of Perthes can be traced to slight defects in the hip-joint alone. Another unfamiliar suggestion in his article is the treatment of obesity by continuous lying down. The recumbent position facilitates the action of the heart and helps urination, so that the watery accumulations, which, as much as fat, cause this condition, are gradually eliminated from the body. Dr. Lambolez's article will stimulate many who do not agree with him.

MEDICAL STUDY IN SWITZERLAND.

SWITZERLAND affords opportunities for postgraduate study which are perhaps not as well known as they might be. There are seven Cantonal or State universities, five of which have a Faculty of Medicine and grant the M.D. degree, the language of instruction being French at Lausanne and Geneva, and German at Bâle, Bern, and Zürich. Bern and Lausanne, in particular, welcome British students, and their regulations are accommodative. The University of Bern has some 65 professors in the Faculty of Medicine, including dentistry, and the number of regular students is about 1600, with 300 *auditeurs*; the University of Lausanne has some 35 professors in the Faculty of Medicine, and about 800 students and 200 *auditeurs*. The choice is governed chiefly by considerations of language and climate. Bern has many attractions as an international centre and its hospital buildings are pleasantly grouped in a sort of garden suburb. Lausanne is situated high up overlooking the Lake of Geneva. The Cantonal Hospital is divided into two main sections, the general hospital (medical and surgical) situated in the Avenue du Buglon containing some 500 beds, and the new maternity and children's blocks, built in 1916, across the road, containing an additional 200 beds each, the whole in design, construction, and equipment being probably unsurpassed elsewhere.

British practitioners are received upon the same footing as the Swiss holding the Swiss Federal Diploma, and can obtain the M.D. degree on complying with the following regulations:—

(I. (*a*)) Matriculation in the University and registration as a student, on production of a matriculation certificate of any British University, or of any preliminary examination recognised by the G.M.C. for the purposes of registering as a medical student; (*b*) Production of the certificate of the degree or diploma qualifying for practice in the U.K. and the certificate of registration as a medical practitioner in the U.K. (II.) Undergoing with success a colloquium—i.e., a viva-voce examination—in any three of the subjects of the final medical examination, at the choice of the candidate—e.g., medicine, surgery, diseases of children, or midwifery. (III.) The presentation of a thesis for the doctorate, which has been prepared and completed in the clinic under the direction of one of the professors of the Faculty of Medicine, in any subject in the medical curriculum.

Most of the professors speak English fluently, and the choice of the subject for the thesis may be made by the candidate and approved by the professor, or may be made by the professor himself. The standard, though high, is within the reach of steady work during the required semester of residence (October–March). After the thesis has been accepted by the Faculty of Medicine, its printing is authorised by the Dean, and 200 copies have to be handed in. The fees are roughly as follows On matriculation, Fr.20; on inscription for the colloquium, usually half-way through the semester, Fr.50; on presentation of thesis, Fr.200; diploma and graduation, Fr.25; courses, lectures, library, and laboratory fees, about Fr.80; printing of thesis, about £7 to £12. It is possible to live comfortably for £10 per month. The calendar and regulations can be obtained from the secretary of the university, and application for admission should be made to the Dean of the Faculty of Medicine, and to the professor in the subject in which the candidate wishes to do his thesis. The Student's Guide is issued in October and April (Guide de l'Etudiant), and may be obtained for 50 cents from F. Haeshel-Dufey, 3 Rue Centrale, Lausanne, or from the Office Central Universitaire, Bern.

---

[1] Considérations sur la Station Verticale et ses Conséquences. By Dr. René Lambolez, Faculté de Médecine of Nancy. La Vie Médicale, August 28th, 1925.

The Academic Diploma of M.D., which has so far been considered, does not confer the right to practise in Switzerland, which requires the possession of the State or Federal Diploma. Examinations for this diploma are conducted by a board of examiners drawn from all the universities. The Swiss students, after matriculating in one of the universities, pursue a five years' course of study, and take the first, second, and final examinations of the Federal Diploma. When this has been obtained they become *médecins fédérals*, and are entitled to practise in Switzerland. A year or two later they proceed to the M.D. degree of their Alma Mater, the Federal Diploma thus corresponding to our M.B. degree. It is not made easy for foreigners to acquire the right to practise in Switzerland, in view of the large number of Swiss qualified medical men and women and the comparative cheapness of higher education in Switzerland. It is obligatory to matriculate and to pass all the qualifying examinations, and even when this is done the diploma is not assured. Every canton, however, has the right to license practice within its own borders.

THE MENTAL PATIENT'S CHANCE OF RECOVERY.

There is no doubt that the average practitioner, and still more the layman, holds the gloomiest views on the chances of a patient with mental disease. The last thing the relatives will do for such a patient is to put him under proper treatment, and the general practitioner, when called in, will often give him up at a glance as incurable. The attitude seems to be that mental patients simply go from bad to worse, and even if they appear to be cured they always break down again afterwards, so that the psychiatrist hardly ever sees a mental case until it has reached an advanced stage.

The way out of this undesirable situation is for the psychiatrist to persuade the practitioner and public by unimpeachable argument, first, that a mental patient has as good a chance of recovering as a medical or surgical one, and secondly, that like the latter, his chance will be considerably improved if he is treated in good time. It is therefore encouraging to read in the *Journal of the American Medical Association* a lecture by Dr. Earl D. Bond, of the Pennsylvania Hospital, in which he analyses 1054 consecutive admissions, including all the graver forms of mental disease, whose history has been followed for at least five years starting from the date of admission. Thirty were lost, and the percentages of the remaining 1024 are as follows: Recovered and stayed well, 26·7; improved, 14·5; died, 32·3; unimproved, 25·5. He remarks that some of the recovered patients attained a higher level of health than they had been able to reach before their illness, and quotes some very striking individual cases who recovered completely from persecutory delusions, hallucinations, paranoia, and melancholia. No patient is counted as recovered who has relapsed at any time since discharge, and the "improved" are generally hard workers who, although they suffer from occasional relapses, are able to earn their living. The deaths are heavy, as is natural over such a long period in a group that includes many elderly people. Influenza in 1918 accounted for several, and many other causes of death were not related to the psychoses in any way. All the patients with senile and arteriosclerotic psychoses, however, died during the observation period. The failures are dementia præcox cases and manic-depressive psychotics with prolonged or frequent attacks.

On the physical and surgical side of medicine there are plenty of statistics about particular diseases, but hardly any of consecutive patients irrespective of what they suffer from. In Dr. Bond's opinion the surgeon or physician would be satisfied with a full return to function in 25 per cent. of his consecutive cases, judged from five to ten years after the beginning of treatment. Whether this is a good estimate or not, Dr. Bond's own results give him the right to challenge the general practitioner to revise his prognosis of the average mental disorder. More statistics of this kind are wanted, and other psychiatrists might well follow Dr. Bond's example. Incidentally, he made out a very good case for holding up the diagnosis of dementia præcox until a long time of observation has elapsed. This disease is incurable, but its symptoms are frequently counterfeited by other and curable diseases, and many cases prematurely diagnosed as dementia præcox have recovered. Their chances are naturally much better if judgment is reserved, and the psychiatrist should wait a very long time before he decides to abandon them as hopeless.

STICKING-PLASTER DERMATITIS.

In the course of a year the medical profession uses many miles of sticking-plaster on patients of all ages and conditions. It is therefore disconcerting to read an article by Dr. H. W. Siemens in the Munich Medical Weekly of August 7th, in which he states that 1 per cent. of persons have an idiosyncrasy that makes the homely sticking-plaster an enemy. Rashes, blisters, eczemas appear from its use that may last a month and give severe trouble. The offending substance is "dammar" resin, that comes from the sap of one of the evergreens and is the favourite mucilage of plaster manufacturers. The irritation is not an acid one, for the resin acids have been proved harmless when tried by themselves. Dr. Siemens found three cases of individual susceptibility in the Munich University Skin and General Clinic, and tested them with dammar resin, dammar-oleic acids, pine resin, colophonium, and a brand of plaster called Helfoplast that contains no resin. The dammar, introduced into the upper arm by scarification, produced an erythema after 24 hours that was still more marked after 48. He tested his first two subjects again after three and a half and four months; the first showed less tendency to react and the second much more. The third case was the most interesting, a college student, male, 24 years old. A strip of plaster over a cut on the left forearm had brought out a severe bullous dermatitis, and tests with various resins and their derivatives, repeated after three weeks, showed a slight reaction to dammar resin and plaster and none to other substances. On the third day of the later test two large strips of plaster were applied to the right upper and fore-arm. They gave a positive reaction at the place of application after two days, and an outbreak of papulous eczema round the original wound and the sites of the earlier test. After 12 days the erythematous patches round the plaster were not very severe, but the reaction on the earlier sites was intensely irritable. The nodules were thickly and widely scattered and had been decapitated by scratching, healing with a serous scab. The reaction on the site of the old tests was less than that on the original wound. Dr. Siemens finds that this idiosyncrasy is not related to eczema liability, nor especially found in eczematous subjects. It would be interesting to know if any parallel results are forthcoming in this country. The subject should certainly be investigated further, since if the 1 per cent. incidence that Bloch demonstrated is uniform, many cases must occur that are not traced to their real cause. Dr. Siemens is still doubtful about the exact nature of this idiosyncrasy, and the fluctuations which he demonstrated in his first and second cases warn us against accepting it immediately as constitutional. The experiments remind us that skin disease as a whole is an obscure subject.

HEALTH OF THE U.S.A. IN 1925.

IN spite of distressingly hot weather in June the health record of the United States has been good so far this year. According to a preliminary report by Surgeon-General Cumming, of the U.S. Public Health Service, most of the commoner communicable diseases have been less destructive to life and health than usual. The death-rate for June was considerably higher than the average for that month owing, in Dr. Cumming's opinion, to the heat waves which then prevailed over a large part of the United States. During July and August the States which report regularly to the U.S. Public Health Service have recorded approximately 6400 cases of diphtheria. Last year for the corresponding period these same States reported nearly 8100 cases, this year's figures showing a decrease for the period of 20 per cent. In the same period measles has indicated a decrease of 27 per cent., while scarlet fever has decreased 14 per cent. On the other hand, there has been a definite increase in poliomyelitis. During the spring and summer months the prevalence of this disease usually increases, but this year 32 States reported 1463 cases of poliomyelitis for eight summer weeks, as against 635 for the corresponding period last year. This increase was particularly noticeable in California, Minnesota, Missouri, New Jersey, North Dakota, South Carolina, and Wisconsin. Typhoid, too, has increased. Decreasing for many years, the general death-rate per 100,000 population in the registration area fell from 35·9 in 1900 to 6·8 in 1923. Since July, however, 33 States have reported 7173 cases, which may be compared with 5013 cases last year, an increase of 43 per cent. Some of this increase may, of course, be due to more accurate and complete reporting of cases. The ports of Oakland and San Pedro, Cal., and New Orleans, La., have been declared free from plague, and outgoing quarantine measures have been discontinued. The Mexican authorities, upon information tendered by the U.S. Public Health Service, have agreed to the discontinuance of the disinfection of mails from Los Angeles, and also to the suspension of the fumigation of freight trains from that city, except in cases in which the Public Health Service deem this measure necessary. Because of the absence of yellow fever from Mexican, Central and South American ports, and the very low incidence of this disease, even in countries in which it is present, there has been no close quarantine this year on account of yellow fever, which means, of course, that there has been no detention of passengers. Dr. Cumming expresses the hope that the authorities of those countries in which yellow fever infection still persists will continue the work of mosquito extermination until quarantine measures will no longer be needed.

Sir Frederick Mott will deliver the Harveian Oration before the Royal College of Physicians of London, Pall Mall East, on Monday, Oct. 19th, at 4 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—During October, November, and December a series of lectures on Tuberculosis will be delivered in the Lecture Room of the Medical Society of London, 11, Chandos-street, at 5.30 P.M. The opening lecture will be given by Dr. L. S. Burrell on "Tuberculosis from the Physician's Viewpoint." All members of the medical profession will be welcome. A two weeks' combined course in Diseases of Children will be given from Oct. 12th, in which the Paddington Green Children's Hospital, Victoria Hospital, and the Children's Clinic will participate. There will be morning and afternoon sessions. At St. Peter's Hospital a four weeks' course in Urology will be held from Oct. 19th to Nov. 14th. From Oct. 26th to Nov. 20th the St. John's Hospital will hold a special course in Dermatology comprising pathology, clinical instruction, and lectures. There will be a two weeks' intensive course in Medicine, Surgery, and the Special Departments at the Royal Northern Hospital from Oct. 26th to Nov. 7th. Application for copies of the syllabuses, as also the Fellowship general programme, should be made to the Secretary at 1, Wimpole-street, London, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLXII.—TREATMENT OF POST-OPERATIVE PULMONARY COMPLICATIONS.

WHEN abnormal physical signs are detected in the lungs soon after an operation it is usually taken for granted that a post-operative complication has occurred, and usually the anæsthetic is blamed for the so-called "pneumonia" or "broncho-pneumonia." But a careful examination of the lungs in a large proportion of acute abdominal cases will reveal definite abnormal physical signs before operation. Unless these are detected, it is difficult to appreciate the significance of any pulmonary change that may be found after operation, especially as very similar signs may result from a purely post-operative condition. Briefly, these signs (which are nearly always confined to the right lung) are increase of size in the right half of the chest, raising of the liver dullness in the nipple line to the fifth rib or fourth space, impairment of percussion note, and diminution of breath-sounds (which are never definitely bronchial) over the base of the right lung, especially at a point 1½ in. below and to the left of the angle of the scapula; the apex beat is in the normal situation. By means of X ray screening the right half of the diaphragm is seen to be raised and its range of movement limited, though what movement there is appears to be an active one. These signs are always present and occur at a very early stage when there is inflammation of the peritoneum in the upper abdomen, but with diminishing frequency as the inflammation is situated further from the diaphragm. They are constantly present in retro-cæcal appendicitis and when suppurative peritonitis is spreading up from the pelvis, and occur in cholecystitis and perinephritis; but they are absent in pyelitis, cholelithiasis unaccompanied by cholecystitis, all forms of colic, tuberculous peritonitis, salpingitis, unless there is a spreading peritonitis, in appendicitis confined to the pelvis, and in pneumonia or diaphragmatic pleurisy. The measurement of the chest is conveniently taken with a saddle-tape measure placed just below the nipples in males and below the breasts in females. The difference is often as much as 1½ in., but an increase of only ½ in. may be regarded as pathological. Obvious fallacies are spinal curvature or old lung disease.

The explanation of these signs is not difficult; just as impaired movement of the anterior abdominal wall is an early sign of peritonitis, so is impaired action of the diaphragm. The latter is not inactive, but its excursion is limited, and what movement remains is apparently able to aerate the lung sufficiently to prevent any great degree of collapse. The liver rises in consequence of the partial collapse of the lung, and by its shape causes an enlargement of the right side of the chest. The treatment is, of course, mainly surgical, but after operation the patient should be encouraged to breathe deeply, and not allowed to remain too long in one position, as there is danger of hypostatic congestion. For the same reason he should be placed in Fowler's position, to avoid as far as possible the pressure of the liver against the diaphragm. Expectorants also help to avoid congestion of the lung base.

POST-OPERATIVE MASSIVE LOBAR COLLAPSE.

There are two forms of this condition: (*a*) collapse with contraction, and (*b*) collapse with enlargement of the corresponding side of the chest wall.

(*a*) *Collapse with Contraction.*—The first symptom is usually sudden pain low down in one side of the chest (usually the right); the temperature rises (102° or 103° F.); respiration quickens and there is some distress which may be acute; after a few hours expectoration of white viscid sputum begins. The physical signs are impaired movement of the affected side of the chest and upper quadrant of the abdominal wall, impaired percussion note, at first diminution or absence of breath-sounds over the lower lobe of the lung, and later well-marked tubular breathing; displacement of the heart towards the affected side, diminution in girth of this side of the chest, inactivity of the diaphragm and upward displacement of the liver, if the collapse is on the right side, or heart, if on the left. The liver dullness may begin as high as the fourth rib, and this upward displacement is a most valuable sign, easy to demonstrate, and constantly present. On screening I have always found the cupola of the diaphragm raised on the side of the collapse and the movement either absent or much restrained, so that the excursion is small and jerky, suggesting tonic contraction.

Differentiation from Pneumonia.

Massive collapse is easily distinguished from post-operative pneumonia by the displacement of the heart and liver, the decrease in size of the affected half of the chest, the viscid white sputum which is never blood-stained or rusty, and the termination which may be as sudden as the crisis of lobar pneumonia, but followed by a much more rapid return of the normal signs of a healthy lung. There is no flush and the skin is usually moist, and has not the hot, dry feeling so often present in pneumonia. The change usually occurs on the third day after the onset of the collapse; the temperature drops to normal or thereabouts, the pain disappears, and the only remaining symptom is the coughing up of the characteristic sputum for another few days. At the same time the diaphragm begins to move in normal fashion.

In certain cases the change is dramatic in its suddenness, which suggests a mechanical cause rather than a pathological change in the lung tissue. The apparent tonic contraction of the diaphragm and the sudden onset closely resemble an attack of asthma, in which condition we also find a rigid (though not raised) diaphragm, which immediately begins to move on cessation of the attack. The similarity has led me to try drugs used to alleviate asthma, and I have found injections of 5 minims of a 1 : 1000 solution of adrenalin the most useful remedy, not only for the treatment of massive collapse, but when given as a prophylactic it seems to lessen the chances of this complication ensuing. It is better to give 5 minims repeatedly than to give larger doses at longer intervals. A second dose may be usefully given in half an hour's time. As a prophylactic 5 minims may be given every six hours for the first 48 hours after operation. Other drugs which are helpful are injections of ½ c.cm. of pituitary extract, or ⅓ gr. of emetine hydrochloride. In addition, small doses of potassium iodide and ammonium carbonate with a few minims of ipecacuanha wine made into a mixture with camphor water, help to liquefy the viscid sputum and so assist its expectoration. Many patients have benefited from the application of a mustard leaf to the side of the neck, which was done with the idea of providing counter-irritation to the phrenic nerve, and with a similar object I have found it of some use to pass a descending constant current down the side of the neck. This form of massive collapse is an alarming complication, but unless pneumonia supervenes (and this happens but rarely) is never by itself fatal.

(*b*) *Collapse with Enlargement of the Chest Wall.*—In massive collapse with enlargement of the affected side there are several points of difference. The onset is painless and gradual; dyspnœa is not marked; the heart and liver are displaced in a similar way, and though the heart is never drawn over so far, the upward displacement of the liver is extreme. When screened the diaphragm can be seen considerably raised, moving very slightly and apparently passively on the affected side, as if paralysed and relaxed. The breath-sounds are feeble, the percussion note is considerably impaired, and bronchial breathing is never as marked or extensive as in the cases associated with contraction of the chest. This is a much more serious complication than that already described and indicates a spread of infection up to the diaphragm and consequent risk of general peritonitis or subphrenic abscess. Treatment is mainly surgical, as there is need of free drainage. Drugs are of little use and adrenalin has no effect. Some cases recover with merely expectant treatment, for the peritoneum can deal successfully with infective organisms in very great measure.

The treatment of any condition involves consideration of the cause. It has been shown that the position and action of the diaphragm are modified in both kinds of post-operative collapse and in the cases which show pre-operative pulmonary signs. The diaphragm is just as much a part of the muscular wall of the abdominal cavity as the rectus abdominis and oblique muscles, and is affected by inflammation beneath it just as are the muscles overlying an inflamed appendix.

That infection greatly modifies diaphragmatic action is clear from a study of 39 cases in which one or other form of collapse of the lung followed operation. (1) Many needed subsequent drainage after the wound had been sewn up, or the wound was found to be suppurating when the stitches were taken out. (2) The more distant the focus of infection, the less likely was the diaphragm to be involved, and inflammation confined to the pelvis never affected it. (3) Subphrenic abscess invariably paralysed the diaphragm. Subsidiary causes of collapse are very large incisions, especially if they extend into the hypochondrium, and rough handling of the sides of the wound at the operation, so injuring the muscles and causing an alteration in the tone of the opposing muscle—i.e., the diaphragm.

A slight stimulation of a muscle causes it to contract, but a severe one removes the power of contraction, which accounts for the two forms of collapse. When the chest is contracted, the infection or stimulus appears to be slight; manifest suppuration seldom ensues and drug treatment is of great use. Where the side of the chest is enlarged, drugs are of little avail and subsequent drainage of the wound, or possibly of a subphrenic abscess, is usually necessary.

Subphrenic abscess is a further complication which may be mentioned. Measurement almost invariably shows the affected side of the chest to be larger than the other, and if the heart has been originally drawn over and the signs of collapse of the lung persist or increase, any movement of the apex beat towards or beyond its original situation indicates the presence of a subphrenic abscess or an abscess in the upper part of the liver. The treatment, of course, is purely surgical. The outstanding feature of post-operative massive collapse is its relation to interference with the peritoneum. The length of operation and the kind of anæsthetic employed appear to have no effect of this sort.

Pneumonia and Bronchitis.

Lobar pneumonia following operation is uncommon, and its treatment in no way differs from that of the ordinary attack. I should like to urge the value of intravenous injection of strophanthin, gr. 1/100, in cases of failing heart with low blood pressure, always remembering that any severe grade of cyanosis must be relieved by preliminary venesection.

Bronchitis, which may progress to bronchopneumonia, is best relieved by injections of atropine, gr. 1/100, or tincture of belladonna in moderate doses, if the sputum is fluid and excessive; if it is scanty and viscid, antimony wine in 20 minim doses with 15 minims of tincture of stramonium is often very useful. A little bronchitis may be unavoidable after long administration of ether, and possibly contributes to any collapse that may be present, but it never seems to be the sole cause.

Special Articles.

THE CENTENARY OF THE DISCOVERY OF BRIGHT'S DISEASE.

BY SIR WILLIAM HALE-WHITE, K.B.E., M.D. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

ON Oct. 12th, 1825, there was admitted into Guy's Hospital, under the care of Dr. Bright, one John King, an intemperate sailor, suffering from general œdema, scanty urine, and pain in the loins. He had hæmaturia but this passed away, and the urine, when clear, coagulated if heated; the pulse was hard. The sectio cadaveris revealed acute pericarditis, œdema of the lungs, pleural effusion, a large heart, and ascites. In Bright's own words:—

> "The kidneys were completely granulated throughout; externally the surface rough and uneven; internally all traces of natural organisation nearly gone, except in the tubal parts. . . . This is a well-marked example of a granulated condition of the kidneys connected with the secretion of a coagulable urine."

He inclines to the opinion that the "disease of the kidney was the first established." He considers that neither the disease of the lungs, pleura, nor heart was the primary condition, nor was there any disease of the liver to explain the ascites. He points out that pain in the loins is a symptom of renal disease, and that

> "the tendency to inflammatory affection in this man was a striking feature in his case and appears to me connected immediately with the condition of the kidneys."

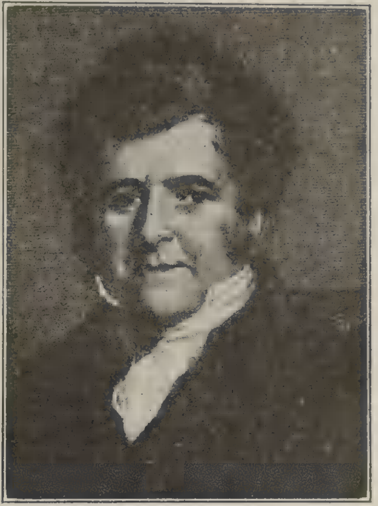
THE LANCET of Dec. 25th, 1858, writing of Bright's death, said:—

> "The sudden and unexpected demise of Dr. Bright has created a deep impression of grief and regret such as only a sense of irretrievable loss could occasion. In him all felt that the medical profession of England had lost one of the most original, observant, and philosophic minds. A man of peculiar independence of thought, of high morale, and untiring energy, he contributed more, perhaps, than any other to form the medical opinion of his day . . . By the singular devotion to pathological investigation which characterised his career, he was at once enabled to accomplish investigations which have immortalised his name."

It is fitting, therefore, that the centenary of the commencement of the investigations on the disease, bearing the name of one better known throughout the civilised world than any British physician since Harvey, should be signalised by some account of Richard Bright and his work.

Biographical Account.

He, the third son of Richard Bright the elder, of Ham Green, Somerset, was born at Bristol on Sept. 28th, 1789. In 1808 he began to study medicine at Edinburgh; in 1810 he accompanied Sir George Mackenzie to Iceland, and he wrote the botanical and zoological parts of Mackenzie's "Travels in Iceland" and drew some of the illustrations. On his return he entered at Guy's Hospital, and, in 1811, read a paper before the Geological Society. In September, 1812, he graduated M.D. at Edinburgh with a thesis on erysipelas, about which he had previously read a paper at the Medico-Chirurgical Society. He spent two terms at Peterhouse, Cambridge, returned to medicine in London, and in 1814 went on a tour through Holland, Belgium, Berlin, Vienna, Austria, and Hungary. He observed and studied everything he came across, medical or otherwise, and in 1818 published "Travels from Vienna through Lower Hungary, with some Remarks on the State of Vienna during the Congress in the Year 1814." The book, a well-printed quarto of over 700 pages, exemplifies Bright's wonderful power of observation and description, his wide reading, his accuracy, as shown by the tables, maps, and appendices, and his artistic ability, for it is illustrated by beautiful engravings from sketches by himself. In 1818 he again travelled in Germany, Italy, and France for nearly a year. In 1821 he became assistant physician to Guy's Hospital, in 1822 a Fellow of the Royal Society, in 1824 full physician to Guy's, and in 1832, although only a licentiate, he was with applause elected a Fellow of the Royal College of Physicians of London. He died on Dec. 16th, 1858; few of the millions that pass along Piccadilly know that there is a tablet to his memory in St. James's Church. He was a man of several interests, physician, pathologist, traveller, geologist, artist, writer, linguist, and an indefatigable worker, for many years spending six hours daily at the hospital. He was beloved by the students and his colleagues, who were invariably willing to aid him in his researches; he was always most careful to acknowledge help given, was ungrudging in his admiration of the work of others, and intensely proud of Guy's Hospital and its museum. But all this does not make a man extraordinary; but Bright was. It is impossible to place geniuses in order, but he would certainly be among the first five or six in our profession. To him was given marvellous power of observation, and his genius took him further even than brilliant seeing of facts, for he could correlate his observations and draw deductions from them.



Richd Bright

(*From Guy's Hospital Reports, January, 1921.*)

Discovery of Bright's Disease.

Bright's most remarkable publication was his renowned book "Reports of Medical Cases selected with a view of Illustrating the Symptoms and Cure of Diseases by a reference to Morbid Anatomy."[1] It is in two large volumes containing 65 beautifully coloured plates. The first appeared in 1827, the second in 1830. It shows his facility of insight, for it is entirely composed of original observations made at Guy's Hospital during the short six years he had been on the staff. In the preface he says:—

> "It is my wish in thus recording a number of cases, to render the labours of a large hospital more permanently useful, by bringing together such facts as seem to throw light upon each other. . . . To connect accurate and faithful observation after death with symptoms displayed during life, must be in some degree to forward the objects of our noble art. . . . The work will not be thoroughly completed, until every disease which influences the natural structure, or originates in its derangements, has been connected with the corresponding organic lesion."

The most celebrated part of this book is the first 126 pages of Vol. I. This section is entitled "Cases Illustrative of some of the Appearances Observable on the Examination of Diseases Terminating in Dropsical Effusion." Bright reminds us that a common cause of dropsy is venous obstruction, but adds that too little attention has been paid to the kidneys. Often albuminuria, which he detected by heating the urine in a spoon over a candle, is present as well as dropsy. Then the kidneys will be found diseased. He says :—

---

[1] This is now a rare book. An abstract of it and of Bright's other writings was published in Guy's Hospital Reports, vol. lxxi., January and April, 1821.

> "I shall now detail a few cases . . . in which I had the opportunity of connecting the fact of the coagulation of the urine with the disorganised state of the kidneys."

Then follow the clinical notes of 23 cases to illustrate this point. Considerably more than half were fatal, a full account of the post-mortem examination is given, together with a series of coloured plates to show the diseased state of the kidneys. I have already mentioned the first, that of John King. Bright's next allusion to renal disease was in his second Goulstonian Lecture delivered in 1833. He then had

> "had great assistance from the intelligent and zealous coöperation of three of my young friends and pupils, Mr. Barlow, Mr. Tweedie, and Mr. Rees."

They examined the urine of 296 patients. Bright alludes to the enlargement of the heart, the serous effusions, the headache, the coma, and the cerebral hæmorrhage found in association with disease of the kidneys and reaches this conclusion :—

> "My conviction is complete as to the existence of some decided connexion between the three facts—anasarca, coagulable urine, and diseased function going on to diseased structure of the kidney."

His final and most extensive communication on the subject of nephritis appeared in *Guy's Hospital Reports* for 1836. It consists of two papers occupying 65 pages; the first is entitled "Cases and Observations Illustrative of Renal Disease accompanied with the Secretion of Albuminous Urine," the second, "Tabular View of the Morbid Appearances occurring in One Hundred Cases in Connexion with Albuminous Urine."

He gives the history of a sufferer from the form of renal disease under consideration thus: the patient may in the past have had scarlatina; early symptoms are polyuria, hæmaturia, and œdema of the face or ankles; if, at this stage, the urine is tested, albuminuria is found. Next he notes that the pulse is full and hard, the skin is pale and dry, the patient complains of headache, pain across the loins, vomiting, and disturbance of sleep owing to frequent micturition. A sense of lassitude, of weariness, and of depression steals over the bodily and mental frame. The blood is found to contain urea. The disease progresses, the œdema may increase, the lungs become œdematous, the headaches are more frequent, the stomach is deranged, the vision indistinct, and blindness may supervene. Finally, the patient dies from asphyxia due to œdema of the lungs, or of the glottis, or in coma or convulsions, or from acute pericarditis or peritonitis. Bright is not hopeful of treatment unless the case is seen in its early stages, but he advises diaphoretics, as antimonial powders, compound ipecacuanha powder, ammonium acetate, and warmth such as a hot bath; bleeding is of little use, cupping the nape of the neck will relieve the headache, leeches to the loins will assuage the pain there; acupuncture will diminish œdema, but we must be careful not to set up inflammation; the only diuretic that may be used is digitalis; elaterium is a suitable purge; milk is one of the best aliments; every precaution must be taken to avoid chill, flannel should be worn, and a warm climate is desirable. I have given a mere abstract of what he wrote, but even that is enough to show that Bright's description is a masterly exposition of the symptoms and treatment of what was then a new disease. The post-mortem appearances of the kidneys are carefully described; it is noted that acute pleurisy, pericarditis, and peritonitis may be found, or the pleural, pericardial, and peritoneal cavities may contain serous fluid; the heart may be hypertrophied, but otherwise healthy; œdema and bronchitis of the lungs are common; sometimes the intestines have been irritated; occasionally they are ulcerated and cerebral hæmorrhage is observed in some instances. Bright, with the inspiration of genius, arrives at the conclusion that the primary cause for all these symptoms and post-mortem appearances is disease of the kidneys.

Assuredly this is one of the most astonishing series of papers in medical literature. A disease, which presents symptoms of derangement of almost every organ in the body, is unerringly ascribed to the kidney. We are shown how to diagnose it. The description of its causes, its symptoms, its treatment, and its post-mortem appearances is so complete and accurate that after nearly a century no error has been detected and, if we except a few facts that have been gleaned by instruments Bright did not possess, nothing of importance has been added.

His enthusiasm for the study of renal diseases continued. With the hearty coöperation of his colleagues, two wards were, from May to October, 1842, set apart for renal cases only, which were all under his care. A small laboratory "was fitted up and decorated entirely to our purpose." This, Bright says, is—

> "the first experiment which, as far as I know, has yet been made in this country to turn the ample resources of a hospital to the investigation of a particular disease by bringing patients labouring under it into one ward properly arranged for observation."

The results of this experiment were published, by Barlow and Rees, in *Guy's Hospital Reports* for 1843, and they confirmed the previous investigations.

Other Medical Observations.

Bright's work on renal disease has attracted so much attention that too little has been paid to his other observations, many of which were original. His power of seeing was extraordinary; little escaped him, he never saw what was not there, not a single one of his observations has been shown to be incorrect; his accuracy and truthfulness are wonderful; no preconceived idea ever tints his descriptions; his industry was unflagging; he willingly goes into the country for the sake of a post-mortem examination. He could write well, it is a pleasure to read him; any disease he describes stands out with all its features clear, and the account he gives is true to-day.

The second volume of his "Reports of Medical Cases," with its 724 pages and 40 artistically coloured plates, is concerned with the nervous system. Bright dislikes the use of the word functional, for it is used to cloak ignorance and it retards investigation. He describes the meningitis due to disease of the ear and nose, and records that the tuberculous variety may be excited by a blow; he tells of patients, with tumours of the brain, who had spasmodic extension of the limbs and in whom the spinal cord was "remarkably firm throughout, almost like cartilage"; this, he thinks, was probably the cause of the spasticity, and to him, therefore, belongs the discovery of the morbid anatomy of secondary degeneration of the cord and spastic paraplegia. More than 40 examples of cerebral hæmorrhage are recorded, both clinically and autopsically, and their relation to renal disease is emphasised. In the section on epilepsy, epileptic mania and somnambulism are depicted; Bright was insistent that certain epileptic seizures, or, as we should now call them, attacks of Jacksonian epilepsy, are due to organic disease damaging the surface of the brain; and further, that in these and in other cases of nervous disease, study of the symptoms will enable us to foretell the position of the causative lesion. In illustration of this he tells us that he saw a man suffering from fits on the right side; because of this he was of opinion that there was disease on the surface of the left brain, which proved to be correct. Aphasia is singularly well described. He was, indeed, the pioneer in the doctrine of cerebral localisation.

He did much to make known the association between chorea and rheumatic fever. Probably he was the first to tell us that a mitral murmur and also pericarditis may accompany chorea.

Bright published a series of papers in *Guy's Hospital Reports* on Abdominal Tumours and these were reprinted as a separate book; 117 cases are reported and form classical clinical lectures. How much of the matter in them is original we cannot say, for we do not know the exact state of knowledge at the time; but with regard to 15 cases of abdominal hydatid disease we have the testimony of Barlow that—

> " It is but due to the memory of Bright to state . . . that the description of acephalocyst hydatids is altogether original, and certainly an anticipation of similar observations which have since been published in Germany."

In his paper on " Cases and Observations connected with Diseases of the Pancreas and Duodenum," Bright was the first to describe—and he did it admirably—the stools which we now know to be characteristic of disease of the pancreas, and he stated that they indicated disease of that organ. He was aware that glycosuria might occur with pancreatic disease. Another paper, " Observations on Jaundice," contains an account of jaundice and its causes. We are told how, in alcoholic cirrhosis, the liver first enlarges and then contracts, and we have the first description of acute yellow atrophy of the liver, for although Bright did not name the disorder, he accurately described its clinical symptoms and post-mortem appearances. A paper on Chronic Peritonitis contains what is probably the earliest description of chronic proliferative peritonitis; the thickened membrane, the bands, the shortened mesentery are all here.

To Bright must be given the credit of being the first to depict Addison's disease. He did not connect the disease of the adrenals with the symptoms, but he gives a life-like account of them and records that the suprarenals were greatly enlarged from a deposit of scrofulous matter. The specimen is still in the museum at Guy's Hospital.

In London, in 1839, was published Vol. I. of " Elements of the Practice of Medicine," by Richard Bright, M.D., and Thomas Addison, M.D. The second volume never appeared, and the first is a rarity; therefore, it is not generally known that it contains the earliest accurate account of the causes, symptoms, course, and post-mortem appearances of appendicitis. It is too long to quote, but everyone interested should read it; Kelly does not exaggerate when in mentioning it he says, " descriptions so clear and well presented that they could not be surpassed to-day."

Conclusion.

In this outline of Richard Bright and his work I have been compelled, for want of space, to omit much; for example, his description of phthisis, his giving of oxygen for respiratory distress, his account of a case of heart-block, and what is probably the first delineation of the broncho-pneumonia and pulmonary collapse seen in whooping-cough; but I trust I have shown that this article, written to commemorate a centenary, is justified.

A CARDIFF CONVALESCENT HOME.—Cardiff Royal Infirmary has long been in need of a convalescent home, and the lack has now been supplied by Sir William Edgar Nicholls, who has presented the infirmary with a country house known as Ty To Maen at St. Mellons, near the city, with 25 acres. The house, which is in beautiful country overlooking the Bristol Channel, will provide between 60 and 65 beds.

WELSH MENTAL DEFICIENTS.—A conference of representatives of the six counties of North Wales has recommended the preparation of a joint scheme for a new home for mental deficients. The North Wales Mental Hospital at Denbigh, which is supported by the counties of Denbigh, Flint, Carnarvon, Anglesey, and Merioneth, has long been overcrowded. Its nominal capacity is 1000 patients, but it sometimes contains 1200.

AN INSANITARY IRISH HOSPITAL.—Donegal County Council is borrowing £7000 for urgent work at the Donegal County Hospital, Lifford. It was stated at the meeting of the council that " there was danger of an attack of enteric fever in the place if some remedy were not forthcoming," and that " anyone going near the place could not help observing that there was something wrong owing to the pungent smell."

PUBLIC HEALTH ADMINISTRATION.

ADMINISTRATIVE MACHINERY IN EUROPEAN COUNTRIES.*

(*Continued from p. 719.*)

VI. HUNGARY.

HUNGARY has been reduced to an area of 36,000 square miles containing a population of about eight millions (206 persons per square mile). Various forms of government have been tried since the war; at present the country is ruled by a single chamber National Assembly based on universal suffrage and acting under a Governor who has royal rights but no legislative veto. For administrative purposes Hungary is divided into counties and each of these is in charge of a Prefect (Fôispán), who is directly responsible to the Government. Each county elects a Municipal Committee, whose General Assembly may have several hundred members. The central authority of the Prefect dovetails into the autonomy of this county parliament, and there is between them an important Administrative Committee, mainly composed of high officials, under the presidency of the Prefect. The representative of the county as an autonomous unit is the Vice-Prefect (Alispán). Towns with a population of more than 50,000 (urban municipalities) correspond to counties and in these the burgomaster is the Alispán. Each county has from three to six districts, the ultimate unit being the commune, which has its own Mayor with Administrative and Representative Councils like those of the county in miniature. Small communes are sometimes grouped into cantons, and towns of over 7000 rank as districts politically.

Health Administration.

The foundation of the present system was laid in 1876 by a sanitary law designed to detect and punish nuisances; but the Ministry of Health and Social Welfare was only established in 1918. The Minister has very wide powers, and is assisted by under secretaries who deal with public health and social welfare respectively and superintend the 14 departments. Each of these is in charge of a Ministerial Councillor and they cover all the branches of health and welfare, including, for example, sanitary administration, social diseases, hygiene, health insurance, and communicable diseases. To advise the Ministry upon all special questions there is a non-executive National Public Health Council representing every branch of medicine, and there is also a Board of Forensic Medicine which assists the Ministry of Justice and advises on disciplinary or disputed points within the medical profession.

Counties (urban or rural municipalities).—The Municipal Committee (General Assembly) is responsible for organising small communes into sanitary cantons, draining marshes, the issue of emergency health regulations, and the revaccination of adults in epidemics. It also examines the credentials of practitioners and midwives, ensures that every commune has a midwife and regulates her fees, and authorises private practice by communal medical officers or makes allowances to them if their income is inadequate. Appeals against the Assembly's decisions are addressed to the Ministry. Under the law the principal lay authorities must be guided as a general rule by expert opinion. The Prefect therefore appoints, subject to the approval of the Ministry, a Chief Municipal Medical Officer in each county, and this officer and his medical subordinates form the nucleus of a Municipal Health Committee which advises and makes suggestions. The Chief Medical Officer is a member of the Prefect's Administrative Committee and acts as expert rapporteur to this and to the General Assembly. Apart from giving advice he supervises the whole health personnel and medical institutions of his county, conducts sanitary inspections, licenses doctors and midwives, undertakes investigations in police cases, and publishes statistical data. He is subject to the Prefect but in direct contact with the Ministry, to which he reports quarterly. He must visit every village at least once a year and he takes action in epidemics. Administrative power, however, rests with the Alispán (Vice-Prefect or burgomaster) on whom the actual responsibility lies for the enforcement of health regulations. It is his duty to see that dwellings are not overcrowded, that conditions in medical institutions are satisfactory, that epidemics are being met, and that sanitary inspection is made properly.

---

* Based on a Series of Reports on National Health Organisation to the Health Section of the League of Nations. Obtainable in Great Britain from Constable and Co.

Note.—Budapest has modified health organisation.

Districts.—The lay Chief District Officer is responsible, like the Alispán, for all public health matters —e.g., the enforcement of sanitary regulations including those applying to food, the care of the indigent sick and of babies, and the ordering of autopsies. The District Medical Officer, appointed for life by the Prefect, reports on any neglect of regulations, inspects buildings, schools, medical establishments, examines food, supervises the treatment of the indigent sick and the certification of death, and conducts medico-legal autopsies. He reports quarterly to the Alispán. (In cities ranking as counties the District Medical Officer is appointed by the General Assembly, which also delegates many of his duties to other officers.)

Communes.—Health administration is the same in communes, cantons, and in towns politically ranking as districts. The chief official is the Mayor, who heads the Communal (Administrative) Council and presides over the Representative (Advisory) Council. He is responsible for drinking-water, cemeteries, inspection of food, and the care of the disabled and children. The commune pays half the expenses incurred in preventing or treating infectious disease, including hospitals, the rest being defrayed by the State. The Mayor must consult the Communal (or Town) Medical Officer, who is assisted by a Health Committee consisting of doctors, veterinary surgeons, pharmacists, ministers, &c. This Committee advises on the appointment of medical officers, hospital surgeons and midwives, and on all health matters, and can appeal to the District Medical Officer. Every commune or canton of over 5000 inhabitants has one or more medical officer. He is allowed to practise privately and advises all the authorities. He treats the indigent without fee, attends maternity cases, vaccinates, certifies deaths, supervises midwives, performs autopsies, and reports to the District Medical Officer.

Hospitals, Training and Registration.

State hospitals are under direct supervision by the Ministry. The doctors are appointed by competitive examination and the senior officers rank as civil servants. Public hospitals must conform to regulations and they are subject to the Municipal Administrative or Communal Committees. The staff is appointed, after examinations, by the Prefect in counties and by the Vice-Prefect in communes. There are also hospitals ranking as Public Utility Establishments, which are semi-private institutions recognised and subsidised by the Ministry in return for an obligation to receive certain kinds of patient. Finally, there are the private hospitals, and these are under municipal supervision.

Insurance.—All workers earning less than a fixed sum who are subject to the Industrial Law are compelled to insure themselves against sickness and accident. There is also a scheme covering civil servants. Strict laws govern *medical practice ;* there is a six months' course in public health but no public health school in Hungary ; health officers are generally required to have passed an examination and to have had two years of hospital experience. A diploma has also been required of *midwives* since 1921, and a ten months' course is needed before this can be taken.

Statistics are based on the reports of the officers mentioned. Registered medical practitioners, persons trained for the purpose, or failing them, the communal authorities, are entitled to certify death. Burial must take place within 60 hours, and autopsies may be conducted whenever desirable in the public interest.

VII. THE KINGDOM OF THE SERBS, CROATS, AND SLOVENES.

Jugo-Slavia was formed in 1918 from Serbia, Montenegro, and the old Austrian provinces of Croatia, Slavonia, Voyvodina, Bosnia-Herzogovina, Dalmatia, and Slovenia. The area is 87,000 square miles and there are over 12 million inhabitants (137 persons per square mile).

Health Organisation.

The Ministry of Health is the central health authority, but has much in common with the Ministry for Social Affairs, which deals with housing, with the protection of children and the infirm, and with social and workers' insurance. The Health Ministry, which has the advisory assistance of a Permanent Epidemics Commission and a Supreme Health Board, is divided into departments dealing with Administration, Health, and the Public Health Services. The Institute for Social Medicine at Belgrade is a technical branch of the Ministry which is collecting information on national and foreign health standards and methods, and is engaged in propaganda and the preparation of schemes and reforms.

The Health Department.—Until 1923 this was independent of the general administration. There were ten sanitary inspectors and there were regional medical officers in charge of each province, district, and county, who had full authority and could inflict fines for infringement of sanitary regulations. Their powers have been curtailed, and they are now responsible to the administrative (political) authorities of their regions, though they retain the right of appeal to the Health Minister.

The Health Services are autonomous technical organisations, which deal with epidemics, malaria, venereal diseases, &c. Their work is regulated by the Ministry through the new Sanitary Institute at Belgrade, which will contain central laboratories with facilities for bacteriology, training of medical officers, and research. The Institute will control the otherwise independent activities of the large provincial institutes for the study of special diseases and the whole body of local epidemiological institutes and stations. Many bacteriological stations have been established, either permanently or in the field, and these are self-contained sanitary units with a bacteriologist, nurses, and disinfecting apparatus. There are also some motor laboratories and two ambulance trains. The service at present has 150 medical officers of its own and is limited to those who have been specially trained abroad. The number is to be increased, and during epidemics other doctors are temporarily coöpted.

Training, Propaganda, and Statistics.

The kingdom has three schools of medicine. After five years' training students are attached for a year either to a hospital or to a health institution, and in this way specialism in hygiene begins at once. The course for nurses lasts two and a half years, and they, too, are attached to one or other kind of institution. *Propaganda* is regarded by the authorities as one of the most essential parts of the health organisation, and is carried on by books, pamphlets, lectures, plays, and the cinema. The Ministry of Health subsidises a paper advocating temperance and publishes an official journal. The method of collection of *statistical information* is as yet incoördinate and faulty. The duty devolves on the Ministry for Social Affairs, but centralisation is incomplete and no reports have been published for ten years. The data are mainly furnished by the priests—Orthodox, Catholic, or Moslem—who are supposed to fill in statistical forms for all births, marriages, and deaths. Helpful instructions are issued for the use of persons who have to state the cause of death in the absence of a doctor. Still-born children are those who "have not breathed and who died before birth." Registrable information is forwarded monthly to Belgrade by the priests or the District Health Officers.

VIII. Czecho-Slovakia.

Czecho-Slovakia is a democratic Republic under an elected president, and is made up of territory from the old kingdoms of Bohemia and Hungary and from a part of Prussian Silesia. It covers 54,000 square miles, and has a population of 13,600,000 (244 persons per square mile). Under the Empire the Austrian provinces of Bohemia, Moravia, and Silesia had a measure of autonomy, whilst Slovakia and Ruthenia were appanages of the Hungarian crown. The Czecho-Slovakian Government is trying to establish a uniform administration, under which the country is divided into counties (Zupàs), with an average population of 600,000, and these are subdivided into districts of 60,000. County and District Commissioners represent the Government in their areas, and there are county councils and district committees which carry on administration under their care. For financial reasons, however, this system is as yet only in force in Slovakia. Ruthenia remains a semi-independent territory governed by a local Diet, and the other provinces retain much of their previous administrative machinery, which combined with difficulty and friction the authorities of the provincial Diet and the Imperial Government.

Health Organisation.

The Ministry of Public Health and Physical Training was established in 1918, and has legal, administrative, financial, and recording divisions. The sections devoted to public health are in charge of heads of sections, or lower officials called Ministerial Councillors, and are subdivided into departments. There is an under secretary who represents the Minister, and a Central Committee which organises the work of the whole under the Minister's presidency. A State Institute of Hygiene is to be formed from the existing institutes of hygiene, serology, pharmacy, bacteriology, chemistry, and hydrology, and a large grant by the Rockefeller Foundation makes it possible to combine the practical laboratory services with hospital work and the training of medical officers of health and sanitary personnel. The Ministry of Social Welfare deals with child welfare, sickness insurance, the care of disabled soldiers, housing, and industrial inspection. It acts through committees established throughout the country according to provinces and nationality. The National Council of Social Hygiene is intended to centralise voluntary health and social work, and is a federation of benevolent organisations which includes those interested in tuberculosis, venereal disease, and maternity and infant welfare. The most powerful voluntary organisation in Czecho-Slovakia is the Red Cross, which organises campaigns against epidemics, establishes hospitals and dispensaries, and arranges courses for public health and social workers.

Local Administration.—The reorganisation of the country into counties will eventually produce in the health services a continuous chain leading from the Rural Medical Officer to the Minister of Health. But the change is far from complete and the remains of the old systems still exist with modifications. Under the Empire there were two distinct organisations, and dual control was evident in its results. First of all, there was the Imperial Service, which was represented in the province by a Provincial Health Commissioner and in the district (60,000 persons) by a District Health Officer. This administration was supposed to supervise health institutions and pharmacies, control the spread of infectious disease, arrange for vaccination, order post-mortem examinations when necessary, and perform other like functions. So much for that; but the Provincial Diet or parliament—an historical relic and a concession to nationalism—also had its health organisation. Chiefly this was concerned with the upkeep of hospitals, but it also superintended the local medical officers. The country was (and is) divided into small areas in charge of Rural Medical Officers, and towns of more than 6000 had one or more Urban Medical Officers. These officials were paid by the communes, on which fell the duty of applying health regulations, collecting particulars of cripples and the disabled, treating the indigent sick, keeping up cemeteries, and supervising infectious diseases. Their officers were also frequently required by the Imperial Service to furnish reports and make post-mortems; but they were quite independent of the State officials, who were far better paid and trained. Both were permitted to practise privately; but the local officers were often practically dependent on what they could earn in this way; which circumstances, and the fact that the district officers were looked on as representing the Imperial Government, led to disharmony and a total lack of coöperation. At present there are in Czecho-Slovakian service 334 medical officers in what was formerly the Imperial Service and about 2000 in rural and urban employment. The new constitution will combine all these in one State Service, but financially this is at present impossible on a permanent basis. To make the local officers subject to the district officers was imperative, and this has been done by enrolling all the local officers as State servants on a temporary contract with increased salary.

Hospitals and Training.

Public hospitals are maintained by the State, province, county, district, or town. Slovakia was the only province in which there were any State hospitals before the Republic was formed. Nationalisation of all hospitals has been abandoned on grounds of expense. There are two beds for every 1000 inhabitants; but unfortunately the distribution is most uneven, and in some districts more are urgently needed. Most of the so-called infirmaries are really poor-houses without medical amenities. Besides the true public hospitals there are institutions receiving that status in return for certain obligations, and there are, of course, private hospitals. In Czecho-Slovakia there are 1506 beds for pre-tuberculous children, 3264 for curable tuberculosis, and 423 for incurable tuberculosis, and in Bohemia alone there are 7108 beds for the insane (more than 1 per 1000 inhabitants). Health centres have been set up in the larger towns for the treatment of social diseases; disinfection stations exist on the frontiers, and there is an observation station in Bohemia to which people suspected of infectious disease are sent. Regular school doctors were appointed in Prague as early as 1904, and there are now 14. Their presence in other towns depends on local initiative; their salaries are paid by the provinces or districts except in the few State schools; in these they are paid by the Ministry of Health, which is the authority in school health matters.

Medical students are required to study for five and a half years, and State medical officers have been obliged to pass an examination before appointment. Two years' preliminary practice was required, and a preliminary university course of three months was usual; but now a regular course on public health at the State Institute of Hygiene is being instituted, and local medical officers also will have to pass the examination. There are schools of nursing, but to possess the diploma is very rare, and general hospital nursing is unsatisfactory. District nursing is almost unknown, and there is no school of public health nursing. Midwives must obtain a diploma before practising. The course lasts six months, and probably 95 per cent. of all births in Czecho-Slovakia are attended by midwives, though there are too few in the country districts. Their general education is very weak. There are very few trained disinfectors, and their duties are usually undertaken by night watchmen or policemen; but a school has been started in Prague, and short courses are occasionally given as demand arises.

POST-GRADUATE LECTURES AT ST. MARY'S HOSPITAL.

The course of post-graduate lectures given over last week-end at St. Mary's Hospital was as successful as those held during the past two years, and had a very cordial reception. Eleven lectures were delivered between 11 A.M. on Saturday and 5 P.M. on Monday; they were freely open to all practitioners, and the fact that over 160 attended part or all of the course should encourage its organisers and provoke imitation of their work.

Mr. C. W. G. Bryan gave the first lecture on the management of

Common Forms of Urinary Obstruction.

Congenital narrowing of the urethral meatus is, he considers, a frequent cause of bouts of obstruction in boys and of continued intractable gleet in men, yet it is often overlooked. In retention due to stricture in adults, any given case may later need anterior urethrotomy, and disturbance by bougies must be minimal. If decongestive measures fail a 2 per cent. novocaine solution should be injected, and a No. 5 French gum elastic bougie passed. If this succeeds the stricture is dilated by four sizes; if it fails, a filiform catheter is inserted and left for 24 hours. A silver bougie is never desirable, and if the stricture is impassable the bladder should be aspirated with the smallest possible trocar, and, if need be, aspirated again after 24 hours. Persistence of retention after this indicates anterior urethrotomy; and infection, of course, forbids aspiration from the first. Strictures must be gradually stretched but never ruptured. Dilatation should not be done more than once or twice a week; an increase of two to three sizes at a session is enough; there should never be bleeding, and it is wrong to go on till there is pain or difficulty. After describing a method of permanent watertight drainage of the bladder by a special catheter inserted through a cannula, Mr. Bryan ended with a plea for cystoscopy and patience in treating ureteric calculi.

The Differential Diagnosis of Gall-stones.

Mr. S. Maynard Smith said that gall-stones must be treated before those complications arise which make them easy to diagnose. After dealing with the main complications he fully described the clinical features of the disease near its onset, emphasising the vague dyspeptic symptoms lacking periodicity and punctuality; the sensations of nausea, giddiness, and chill often noticed; the relation of discomfort to fatty foods, and the absence of relief by alkalies. Visceroptosis is more confusing than ulcers. In gall-stones there may be short acute exacerbations, unrelated to food, when the vague epigastric discomfort turns to right hypochondriac pain with transient subcostal tenderness; lying down brings no relief; a day of standing brings no exacerbation; and bile may be found in the urine. Chronic appendicitis gives tenderness over McBurney's point, not to be confused with diffuse tenderness over the lower rectus muscle due to a distended cæcum. In conclusion, Mr. Maynard Smith discussed, with illustrations, the value of X rays, and mentioned the detection of bilirubin in the blood, the examination of bile withdrawn through a duodenal tube, the estimation of blood cholesterol, and the intravenous injection of calcium tetrabromphenolphthalein to display the gall-bladder with X rays.

Speaking on

Hæmorrhagic Ovarian Cysts,

a common cause of pelvic pain, Mr. T. G. Stevens said that these have been variously called hæmorrhagic corpus luteum cysts, tarry or chocolate cysts, and apoplectic ovary. They are usually found in sterile women of 25–40, and give rise to severe increasing dysmenorrhœa—otherwise rare after the age of 19—coming on several days before the flow and lasting for two days; rectal pressure and pain due to adhesions; dyspareunia, and, in half the cases, menorrhagia. Swellings of moderate size on either side of a partly fixed uterus to which they are somewhat attached, in conjunction with these symptoms and in the absence of any history of pelvic peritonitis, are probably hæmorrhagic cysts. Inflammatory tubal swellings never have the same insidious onset. The condition has often been wrongly diagnosed and disregarded, but it is very serious; the patients become chronic invalids and suffer much; the only satisfactory cure is operative, and both ovaries generally need removal. Until recently the pathology has been obscure. In every cyst wall, said Mr. Stevens, a small area of endometrial tissue is found, and the cyst is formed by the menstruation of this tissue, the pressure of blood producing the severe pain. He discussed the possible sources of this "endometrioma," and its relation to adenomyomata and endometriomata found in other positions. He is satisfied that it comes from endometrial tissue carried up through the Fallopian tubes at menstruation and implanted in the ovary, as is proved, he considers, by ovarian sections which have been prepared.

Dr. C. M. Wilson followed with a lecture on

The Patient's Point of View in Treatment.

He began with a plea that where there is a doubt the patient's opinion should have the benefit of it rather than the doctor's prejudice. In uncertain duodenal ulcer medical treatment should be tried. So-called functional disease probably rests on an organic basis, and it is useless to tell a chronic nervous dyspeptic that he is a bundle of nerves; he must have careful examinations and explanations. Exophthalmic goitre is a common disease badly mishandled. Every case is a potential case of heart failure, and must be moved at once into better conditions. Surgical treatment has a mortality of 5–10 per cent., and X rays must always be given a trial first; to operate when the basal metabolic rate is rising is disastrous, and the time must be carefully chosen. Diabetes in a child demands elaborate institutional treatment; in a young adult it demands at least three weeks' careful training and investigation in hospital; in the middle-aged it usually needs a modified diet, and, if this is neglected, a warning about eye troubles; in the aged only complications have to be treated. Briefly, insulin is only indicated in children, in coma, in gangrene, and sometimes when the diet fails. With heart disease in pregnancy labour is usually successful, but serious degeneration follows.

On Sunday morning Mr. Zachary Cope spoke on

Minor Surgery in General Practice.

After referring to the dangers of chloroform and cocaine he dealt briefly with the treatment of various common conditions. No operation should be regarded as unimportant; care is always needed. Breast tumours are outside the province of minor surgery altogether; they must always be treated as malignant till proved benign, and nothing less than the whole section of breast containing them can safely be removed for fear of diffusing cancer cells. In abscesses, contrary to belief, redness and fluctuation are by no means always present. Ischio-rectal abscesses must be diagnosed early to avoid fistulæ; peri-anal pain demands rectal examination; the removal of a circular piece of skin at the centre of the usual cruciform incision gives good drainage. As a guide to infections of the hand Kanavel's book is invaluable. Needles should be localised if possible by seeking for them under X rays with a hypodermic needle containing novocaine. Brilliant green (a 5 per cent. aqueous solution) is useful in erysipelas, and acriflavine is a good general antiseptic. Mr. Cope ended his lecture with ten minor surgical commandments, which prohibit the use of cocaine for small tumours under the skin, of chloroform after adrenalin, and of strapping applied to infants' skin. They prescribe microscopy for all small tumours, radiography for all sprains, and Hilton's method for opening all deep abscesses.

Prof. B. J. Collingwood opened a lecture on

Some Applications of Physiology in Practice

by remarking that it is untrue to say that laboratory work is divorced from clinical work; they are not yet even engaged. His address dealt with the reaction of the blood, and he gave a lucid explanation of the terminology used. The general metabolism makes for acidity, but a constant reaction is vital to the body and is maintained by the alkaline reserve; when this is reduced the body normally excretes acid ions by the lungs. The CO_2 in alveolar air is an index of the acid content of the blood and can be easily and quickly determined. Much diminution of alveolar CO_2 below the normal 5 per cent. therefore means that the alkaline reserve is reduced, since the acid content of the blood varies as the alkaline reserve in order to keep the reaction constant, and it is thus easy to discover and measure acidosis or alkalosis. The second way of getting rid of acid is by the kidney. The urine is a caricature of the blood—it exaggerates any fault—and a slight rise in hydrogen-ion concentration in the blood produces an acid urine. A third defence against acidosis is the combination of acid radicles with ammonia by which, if necessary, ammonium salts are excreted instead of urea.

On Monday morning Mr. Warren Low read a paper on

Malignant Disease of the Colon.

Clinically, he said, it may simulate a dozen diseases. As a rule it is of low malignancy, but there are striking exceptions, and it often occurs earlier in life than other forms. After describing the annular and cauliflower types of growth and showing specimens, Mr. Warren Low discussed ulceration in the distended bowel above the lesion and the types of obstruction which developed. The onset of constipation in a patient over 40 always demands examination; cæcal cancer often produces colicky pain after meals; in obstruction there is often visible peristalsis and a local or general distension. In growths on the left side constipation is seldom absent; on the right side diarrhœa is common, and ten days' intractable diarrhœa in an adult should stimulate investigation; neurasthenic dyspepsia or ulcerative colitis are commonly diagnosed mistakenly. A rectal examination is essential; X rays are rather disappointing at present; the diagnosis from diverticulitis may be impossible, and laparotomy should be done oftener. The vaunted value of blind cæcostomy is illusory in practice, and it is to be reserved for desperate cases and those in which the diagnosis is certain.

Overlooked Causes of Fever in Children.

Prof. Langmead said that in protracted fever, where the child is obviously very ill, one must think of pneumonia, generalised tuberculosis, *B. coli* infection, malignant endocarditis, and typhoid. Too much is laid at the door of worms and dentition, but they are also possible causes. The only absolute sign of generalised tuberculosis is a choroidal tubercle. *B. coli* infection is too often overlooked, as for some reason babies' urine is not examined; offensive urine and rigors may give a clue, and the condition may be a cystitis, pyelitis, or even a fatal pyelonephritis. Though cases of congenital heart occasionally have bouts of fever, they frequently end with malignant endocarditis. Where unexplained fever is the outstanding feature of a case, constipation or mild colitis due to diet—perhaps excess of bananas—is often responsible. Bilious attacks without vomiting, which otherwise resemble bouts of cyclical vomiting, are not uncommon, and food idiopathy is an occasional cause of fever. No throat should ever be forgotten, and otitis media is sometimes exceedingly insidious. Obscure fever also occurs in dental caries, chronic appendicitis, cryptic glandular tuberculosis, and in nervous children whose mental or physical equilibrium has been disturbed. In stomatitis the buccal temperature is sometimes raised spuriously above that of the rectum. Speaking on

Clinical Types in Gynæcology,

Mr. Aleck Bourne said that sterility is often due to fine adhesions or membranes closing the ostia of the Fallopian tubes. In women complaining of sterility who show no constitutional or pelvic abnormality he recommends dilatation of the tubes by gas, to find out whether the ostia are patent. The apparatus is simple. Under an anæsthetic the cervix is slightly dilated and gas is passed into the uterus; a constant low pressure and bubbling sounds on auscultation show that the gas is entering the peritoneal cavity. This procedure is inapplicable if there is sepsis or tubal inflammation and in the week preceding menstruation when congestion occludes the ostia; but apart from constitutional disease it is otherwise safe and rational, and American statistics suggest that it is therapeutic as well as diagnostic. In healthy sterile women with closed ostia a plastic operation is worth trying. Describing the symptoms which may coexist with retroverted uterus, Mr. Bourne said that, practically speaking, its correction is only needed in the type of woman with dyspareunia, a tender "fixed" uterus, and prolapsed ovaries, in marked prolapse, and in some cases of sterility and repeated abortions. He ended by mentioning the value of X rays applied to the thyroid in "functional menorrhagia," and the possibilities of intra-uterine radium in this condition.

On Monday afternoon Sir William Willcox lectured on

Chronic Toxæmia,

its recognition and treatment. He regards latent infection as the most important known ætiological factor in disease. The relation of toxæmia to diabetes, exophthalmic goitre, appendicitis, gastric ulcer, arthritis, and many other conditions is generally recognised. Its symptoms include wasting, debility, neurasthenia, and a muddy complexion; the last is very suggestive. The irregular pyrexia may suggest typhoid, and amongst many results of toxæmia are thrombosis, hæmorrhages, myocarditis, and endocarditis. The gradual rise of blood pressure throughout life is probably a result of toxæmia which might be avoided, and it has been suggested that 75 per cent. of mental disease is toxæmic in origin. Teeth, tonsils, antra, bowel, and urogenital system—all require investigation in doubtful cases. In intestinal infection there is often an atonic colon, a palpable cæcum, and indicanuria. Colon lavage may yield good material for examination, and is a simple effective form of treatment which any intelligent nurse can carry out. Vaccines should only be given after removing the focus, if that is possible, and need caution in diseases like gout in which resistance to bacteria is poor. Vaccine dosage, indeed, is generally too large.

Cancer of the Breast.

Mr. Duncan Fitzwilliams said that it may be many years before Barnard's findings can be accepted as proved. To establish that cancer is bacterial would not necessarily give us a cure, and the only certainty about the disease is that it is non-infective. Breast tumours in women over 35 are malignant in 80 per cent. of cases. The remaining 20 per cent. are made up by abscess, which is usually puerperal and therefore rare at this age; adenoma, which commonly occurs in younger women; lipoma, syphilis, tuberculosis, and duct papilloma. This last often gives a blood-stained discharge and it is impossible to say in any given case whether it is malignant or not. The hope of cure in breast carcinoma depends on really early diagnosis. To wait for pain, involvement of the skin, nipple retraction, or axillary swellings is futile. If a woman complains of uneasiness in the breast and anything abnormal can be felt, there is only one proper course—microscopy. There is no other way of diagnosis at the time when the patient will have a 60–80 per cent. chance of cure.

A demonstration followed this lecture and ended the post-graduate course.

IMPERIAL SOCIAL HYGIENE CONGRESS,

Wembley, Oct. 5th–7th.

Under the auspices of the British Social Hygiene Council a very largely attended Imperial Social Hygiene Congress took place in Conference Hall No. 3 at the British Empire Exhibition at Wembley on Oct. 5th, 6th, and 7th. The chair was occupied by Sir Auckland Geddes, the President of the Council, who extended a cordial welcome to the various delegates, many of them hailing from distant Colonies and Dependencies.

Opening by the Secretary for the Colonies.

Mr. L. S. Amery, M.P., Secretary of State for the Colonies, formally opened the proceedings in a speech in which he reviewed the general question of venereal diseases in various parts of the Empire. He said that those who embarked upon this work could well be satisfied by the obvious signs of the increasing interest and recognition of the importance of the subject from the public health standpoint which had been manifested both by the general population and in official quarters. In Africa, especially, the wrestling with the problem had got to be carried through by the people themselves, and it must be remembered that the African native was not, either in physique or intelligence, capable of coping with the great task which was to be attacked there, hence the great requirement was the enhanced development of the people, especially on the physical side. The foundation of African disease was not one which was inherent in climate so much as inherent in man ; it was due to neglect and was therefore eradicable. The increasing importance of the part which medicine had to play in the administration of the tropics was patent to all at headquarters who could take a general view ; and what applied to Africa was also applicable, in smaller measure, to other parts of the Empire. The Colonial Office was now giving greater attention to the suggestions of the Advisory Council, and had increased the grant to the body responsible for this Congress. Under the auspices of Mr. Baldwin and Lord Balfour the British Government had created a new policy in the form of the Committee of Civil Research, which would do for the scientific aspect of our national life what the Committee of Imperial Defence did 20 years ago for the external security of our national life. He emphasised the fact that the administration of the Empire as a whole must be based upon a sound health policy. The particular diseases with which the present Congress was concerned were among the most serious and yet most hopeful to which any body of workers or reformers could devote themselves ; the wastage and destruction of human life for which they were answerable was being more and more realised, and with the march of scientific research in regard to them they could be eradicated given a sufficiently strong public opinion and a determination to combat them. The chief barriers in the past had been ignorance, indifference, and fatalism, creating a very hopeless public outlook. Concealment, deliberate or semi-conscious, on the part of the public on this matter had not only affected legislative attempts to deal with it, but had even influenced the amount of study which had been devoted to it by the medical profession. Very great progress in the matter had recently been made, however, and that largely in consequence of treating the disease frankly as a disease, without permitting any other considerations, such as any stigma, to enter. He expressed his high appreciation of the work being done by the Council throughout the Empire, remarking that one of the great problems of to-day was to build up and to eliminate waste, and there was no form of waste more disastrous than that due to preventable disease.

Mr. Mifzud (Prime Minister of Malta) told the Congress that he attributed great importance to the work being done for the Empire by the Council and by the holding of congresses of the kind, as well as the Imperial efforts to stamp out all diseases in the territories of the Crown, instancing especially Mediterranean fever and venereal diseases.

Mr. James McNeill (High Commissioner for the Irish Free State) followed and expressed similar sentiments.

Dr. J. Alexander Mitchell (South Africa) spoke of the instruction and inspiration which the work done in this country had afforded to South Africa, where, however, racial differences and peculiarities rendered its application difficult. It was a pity that Governments had not recognised earlier that this campaign was not only a good one, but that it paid.

Dr. D. Colquhoun spoke of the drastic law which the New Zealand Government had placed on the Statute Book relating to the compulsory notification of venereal diseases, and the infliction of penalties in the case of those who, being infected, refused to persevere with the necessary treatment.

Sir Leonard Rogers referred specially to the case of India, and said that the greatest feature of the body responsible for the Congress was that it was one of the first bodies to break the " conspiracy of silence " which had so long attached to the subject. In the large cities of India, and especially in the ports, prostitution was appallingly prevalent, but there was the great off-setting advantage that the great mass of the population was rural, and in those areas early marriages were the rule, and these constituted a safeguard. But when the rural folk visited the towns they often went back infected. The spread of knowledge among the rural as well as the town populations would constitute the great means of checking the spread of venereal diseases.

Naval and Military Aspects.

Surgeon-Commander T. B. Shaw read a paper on the venereal disease problem as it affects the Navy, in which he bore testimony to the valuable work done by the Council at the various ports visited by the Navy. He said that the greater the incidence of venereal disease on shore, the larger would be the number of cases on board ship. The loss to the Service caused by venereal diseases was very heavy ; in 1921 the case-ratio of these diseases per 1000 men was 113 in the year, and the total days lost to the Service by men being on the venereal sick-list was 325,557, the daily average of men sick from these conditions being 892. In the years preceding the Great War there had been a steady decline in the incidence, but since 1915 these diseases had shown a steady increase, associated, no doubt, with a general increase in promiscuous sexual intercourse following a general laxity in sexual relationship. He was convinced that as this promiscuity would continue to be practised by some people in spite of all efforts to the contrary, the only hope of eventual extermination of these diseases lay in the wider application of means of disinfection of the parts immediately after connexion. His experience in the Service had convinced him that when prophylactic measures were properly used there was little or no risk of contracting the disease. Dr. Shaw proceeded to give his views on particular measures applicable to various conditions in the Service, such as restriction of leave and placing certain districts in foreign ports " out of bounds." He had an unflattering word to say about China and the city of Cape Town, the latter chiefly on account of the great prevalence of these diseases among the coloured population.

Major E. C. Lambkin (representing the War Office) read a paper on venereal diseases in the Army, in which he said that in the great advances made in connexion with the subject the social influences, especially temperance, played a great part. During the last 20 years, excluding the war period, the incidence of these diseases in the Army at home showed a steady decline. In 1904 these admissions were at the rate of 55·8 per 1000, and in 1922 25·9 per 1000.

The admissions in garrisons abroad had always been high, partly owing to lack of provision for regular exercise, partly to laxity of treatment in small scattered units. In the area of occupation on the Rhine and in Turkey the problem was one of real difficulty; in Cologne alone it was computed that there were 6000 prostitutes. The Aldershot Command continued to show the lowest incidence figures, and here the conditions were good, and the organisation of amusements and recreations rendered it less necessary for the soldier to spend his leisure outside. Twenty per cent. of the cases became infected while absent on leave, and many were found to have contracted their disease from amateurs, not from prostitutes. He emphatically declared, contrary to the view held by some, that the Army did not condone or encourage sexual irregularities, but did its best to make the conditions for the soldier as alert and invigorating as possible. There should be some organised attempt at prevention by medical means, such as the packet in use in the Navy. He knew of one command in which a practically clean bill of sexual health was due to the enthusiasm and friendly attitude towards the men of one orderly, who secured attention to immediate measures as soon as risk of infection had been encountered. In Army life concealment of these diseases was of rare occurrence; the trouble was to persuade the men of the need of taking due precautions.

In the ensuing discussion Sir Leonard Rogers expressed surprise that as immediate disinfection was of so much value when properly carried out, the figures for the Navy were not better than they had been shown to be. Colonel L. W. Harrison said his view was that in recent years the proportion of relapses to fresh infections had considerably diminished, due to the more efficient treatment now prevailing. Dr. T. G. Stokes asked whether measures had been adopted to prevent the spread of these diseases to the civilian population by discharged soldiers. Mr. E. B. Turner said his experience was that 48 per cent. of sufferers had attempted the prophylactic treatment, and it had failed. Success or failure in this matter depended largely, he thought, on the personality of the man in charge.

Dr. Shaw replied that if all the men could be got to use suitable prophylaxis immediately after connexion, venereal diseases would soon be exterminated. During six months 1400 preventive outfits were issued, and only one man using such got syphilis, and he delayed its use an hour. Work was now being done on a mercuric iodide soap.

Major Lambkin, in his replies, said there was, in the Army, no compulsion about the use of preventive measures. No man was discharged from the Army until he was deemed to be free from infection, and a man still having the disease when he left the Army was notified to attend the nearest venereal diseases clinic. Patients with gonorrhœa were subjected to every known test before discharge, and relapses were now far fewer than formerly. The moral teaching of the men was left largely to the chaplains.

The Administrative Position Within the Empire.

A paper on this aspect of the subject was read by Mr. C. M. Kohan, who presented a succinct epitome of enactments and regulations bearing on the subject in the various parts of the Empire, remarking that India appeared to be practically untouched by ad hoc legislation dealing with venereal diseases. The most drastic laws seemed to obtain in Queensland, but expert witnesses stated before a Royal Commission in Australia that notification by medical practitioners of cases of these diseases under their treatment was not being efficiently observed. That Commission also received much evidence as to considerable infection by female amateurs.

Dr. J. H. Mitchell (S. Africa) paid a warm tribute to Mr. Kohan for his laborious research.

Methods of Health Propaganda in the Far East.

Sir Claude Hill, K.C.S.I. (Director-General, League of Red Cross Societies), read a paper on this subject. He said that methods of sanitation could only become effective with the informed coöperation of the people themselves. In the League secretariat, therefore, all possible information had been collected as to the chief causes of the suffering and disability of the people. He set out in detail the methods of propaganda employed, and exhibited specimens of posters and other means of pictorial instruction. The organisation he represented had been able to arrange for the delivery of 30,000 popular lectures on the subject. Also a health exhibition was organised at Bangkok in 1922, and 50 per cent. of the population went to it.

Sir Harry Waters paid a tribute to the work being done by the Red Cross League, and especially that accomplished by Dr. Peters. Mrs. Billinghurst said that an attempt was made in Shanghai to start a V.D. clinic for women, but opposition to the proposal by the nursing sisters, who belonged to a Roman Catholic order, stultified this.

The Diseases in Relation to Race and Climate.

Dr. H. M. Hanschell read a communication on the relation of these diseases to race and climate, based largely on his experience as pathologist at the V.D. clinic at the Seamen's Hospital, Royal Albert Docks. He considered that reported differences in the several venereal diseases in different racial groups were founded mainly on locally conditional circumstances affecting the investigation of these diseases.

Dr. P. T. Harper spoke of the mildness of these diseases in Fiji, where the people were practically vegetarians and consumed very little alcohol. The bulky vegetable diet caused frequent evacuations, and intestinal toxæmia was thus rendered less liable to occur. He thought active immunity against syphilis was caused by their having been inoculated when quite young with yaws.

Lieut.-Colonel W. R. Dawson pointed out that cases of syphilis which were supposed to have been cured by injection of malaria still had active treponema pallidum in their system.

On Tuesday morning the meeting was presided over by Viscount Willingdon.

Syphilis and Cardiac Disease in India.

Sir Leonard Rogers read a paper in which he made a comparison of the incidence of syphilis and cardiac diseases in India with that in this country. Rheumatic endocarditis, in 1000 post mortems in London, gave a mortality of 3·7 per cent., whereas in Calcutta there were no deaths from this cause. Aneurysm gave 3·2 per cent. for London, 1·59 per cent. for Calcutta. Ulcerative endocarditis was also definitely more frequent in London than in India. Practically all the heart disease in India was due to syphilis.

The Chairman expressed his great appreciation of the work which had been done by the I.M.S., especially in such a country as India, where there was a great suspicion and distrust of anything new. Recently it had been decided, with the full concurrence of the Governments of Bombay, Madras, and Bengal, as well as that of Burma, to send out a small expert commission to give what expert help it could in assisting to stamp out venereal diseases, which, especially in the centres of industry and the ports of the country, were on the increase.

The position of the campaign in various parts of the Dependency was then dealt with in papers by Colonel R. M. Carter (Bombay) in relation to Bombay; Major W. L. Harnett, who dealt with Calcutta, Lieut.-Colonel T. G. Stokes, reviewing the Central Provinces; and Lieut.-Colonel W. H. Forster in relation to the Punjab. Colonel Carter thought more good would be done by controlling and seeking to improve brothels than by drastic suppression of them. All the papers showed sincere and careful work. There was a short general discussion.

Congenital Syphilis in India.

Dr. Kathleen Vaughan (Kashmir) spoke of her experiences during the three years she was in charge of the Jubilee Zenana Hospital at Srinagar. There was, she said, a regular trade in women with the Punjab, and when these women were no longer fit for their trade they returned to their native land, and no doubt swelled the ranks of the diseased there. The Indian woman was a passive agent in her own degradation, a very important fact to remember. Some of the women who had led such a life practised midwifery in their declining years. The speaker said that the Kashmiri Hindus were gradually disappearing, and four chief reasons for this were venereal disease, tuberculosis, osteomalacia (among the women), and the practice of infanticide by throwing unwanted children into the rivers. She had found the whole place to be overrun with disease. Children of 10 and 11 years of age were sent to their husbands' houses, and often were killed as a result. Many girls before reaching puberty had been infected by their husbands with gonorrhœa, and gonorrhœal ophthalmia was all too common. Dr. Vaughan said the first step should be the investigation of the conditions here described, then the distribution of suitable literature, then the provision of free treatment, and control of the depressing traffic in women which was going on.

The final paper of this morning's session was by Mr. H. W. Bryant, the general secretary of the Bombay Y.M.C.A., who said that some of the largest problems which workers in his agency had to contend with were housing and poverty, early marriages and infantile mortality, and prostitution. These he dealt with in detail.

(*To be continued.*)

IMPERIAL SOCIAL HYGIENE CONGRESS: THE DINNER.

The Congress dinner was held at the Princes Restaurant, Piccadilly, on Monday evening, Oct. 5th, when Sir Auckland Geddes, chairman of the Council, occupied the chair. After the loyal toasts, the toast of "The Empire" was proposed by Mr. L. S. Amery, Secretary of State for the Colonies, who spoke of the work of his predecessors, Mr. Joseph Chamberlain and Lord Milner, in building up a health tradition in the Colonies. The outlook as regards venereal disease was both serious and hopeful, for he realised how much could be done by a few people who really cared. Viscount Willingdon, who responded, acknowledged the part played by the British Social Hygiene Council in raising up a healthy virile people to carry on the work of the Empire. Sir Auckland Geddes proposed "The Congress," whose great object it was to keep steadily before responsible officials and the public the instructed point of view. Sir Alfred Mond, in responding, remarked on one very important item of progress—namely, that the fresh air of discussion had been let in on the subject of venereal disease. In this country syphilis had been reduced by one-half in the last four years, and he saw no reason why it should not be stamped out. Sir William Schooling proposed "The Delegates and Guests," to which, in the absence owing to illness of Dame Rachel Crowdy, response was made by Sir Claude Hill, who spoke of the increasing influence of British thought throughout the world and of the unique position of women in British social work, and by Mr. Junkin, of the Sun Life Insurance Office of Canada, who made the gratifying announcement that his company proposed to make a donation to the funds of the Council from their large unallotted surplus. Prof. Winifred Cullis neatly proposed thanks to Sir Auckland Geddes for presiding.

NEW MATERNITY HOME FOR CHESTER.—The new Chester Maternity Hospital, situated in White Friars, was opened on Sept. 30th by the Marchioness of Cambridge. The expenditure on the building and equipment amounted to £7000, and the hospital is opened free of debt.

Public Health Services.

SCHOOL MEDICAL SERVICE.

THE following figures are given in the reports for 1924:—

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
West Ham ..	—†	—†	16,833	17,087	21·5
Llanelly	—†	—†	1,375	1,974	15·49
Nuneaton ..	7,789	—†	1,658	7,005	11·5
Soke of Peterborough C.C.	—†	1,425	500	595	—†
Rutland C.C. ..	—†	2,627	773	787	—†
Swindon B.....	8,868	7,701	2,491	5,168	33·3
Northampton B.	—†	—†	3,165	8,825	16·4
Dover	—†	5,461	1,888	1,725	13·2
Leicestershire C.C.	35,890	—†	10,255	7,600	11·9

* Excluding dental defects and uncleanliness.
C.C. = County council. B. = Borough. † = Not given.

West Ham.—Dr. F. Garland Collins's report is a straightforward account of the various phases of school-work well carried out, but there is no mention of any linking-up of the maternity and child welfare scheme with the school activities. The large number of special examinations is a token of the good work done. These children are recommended by teachers, parents, attendance officers, and nurses for examination; representing as they do the ailing section of the school population, they are deserving of special attention. Blind, deaf, physically and mentally defective children are all cared for, either in the borough itself or by arrangement with neighbouring authorities. Open-air classes are held in many schools and two new open-air schools are now in operation. Though only the 6, 7, and 8 year-old children are examined by the dentists, the quality of the work is high, as 83 per cent. of those found to require treatment get it.

Llanelly.—Many interesting tables are given in Dr. L. W. Pole's report which show at a glance the percentage of the various defects. The figures given for enlarged cervical glands (25·2 per cent.) is high, but no doubt includes all the cases of palpable glands. The vexed question of "What is anæmia?" is raised by the large percentage (32 per cent.) of routine children marked as anæmic. In these times it is encouraging to see that 79·8 per cent. of the children examined were found to be vaccinated. A dental surgeon has been recently appointed, and in order to overtake the long arrears has instructed the school nurses in examination for dental caries, and he proposes that they should carry out the inspections while he devotes his time to treatment. This is no doubt expedient as a temporary arrangement.

Nuneaton.—The varying standards adopted by examining medical officers is clearly shown when we see that less than 0·2 per cent. of Nuneaton children who were examined suffer from anæmia, against 32 per cent. in Llanelly, while 1·5 per cent. of the Nuneaton children have enlarged cervical glands, compared with 25·2 per cent. in Llanelly. Dr. K. E. Tapper remarks on the progress made in the school medical service since he took over the work, but points the road for the future advancement by, among other things, extending open-air facilities and opening special classes for abnormal children. He concludes with justice that the cumulative benefits of the early treatment of all ailing children cannot be measured in £ s. d.

Soke of Peterborough C.C. and Rutland C.C.—The school medical officer for Soke and Rutland, Dr. Christopher Rolleston, reports that, though correction of visual defects is popular, in only 21 cases out of 111 have parents in Soke sanctioned the proposed operations for enlarged tonsils and adenoids. He discusses the causes and effects of this condition, and finds that 58 per cent. of children in whom it is present show some retardation in their studies. Facilities for treatment and the coöperation of parents are both much better in Rutland than in Soke. Dr. Rolleston has investigated the physical condition and environment of all the backward children in his areas, and in about 50 per cent. of cases could find no causal factor.

Swindon.—Dr. Dunstan Brewer finds that primary cases of ringworm are often traceable to infection from cattle. He thinks that there is no justification for separating severe myopia from slight myopia and considering them as different entities. In addition to myopia, dental caries, enlargement and disordered action of the thyroid, and spinal curvature are important factors in secondary schools. Dental caries is neglected more often in secondary than elementary schools; apart from this, hyperthyroidism is the most prominent condition in Swindon secondary schools. Interesting comments are made on "overstrain."

Northampton.—The offices of medical officer of health and school medical officer have been combined so as to increase coöperation between the services. Dr. J. Doig McCrindle introduces the report of the assistant school medical officer, Dr. J. H. Mason. The pressure of work has made special inquiries impossible. The number of children unvaccinated is deplored. Investigation of 203 children who have left mental defective schools reveals that of those alive 40 per cent. are at work, 44 per cent. in institutions, and the remainder unemployed.

Dover.—Dr. A. B. McMaster reports that the facilities for visual correction are increasingly used. Investigation has been made of the relation of visual defects to improper illumination in schools. An account is given of lessons in mothercraft by school nurses who are also health visitors, and the scheme is to be commended. The lack of special schools is regrettable, though an open-air school is promised.

Leicestershire.—Dr. T. Robinson reports no provision of open-air schools or classes for blind, deaf, or physically or mentally defective children, and no definite orthopædic scheme is yet in operation. The number of crippled children (157) and of mentally defective (26) is incredibly small out of a school population of 35,800. Dr. J. B. Dalton states that in a small-pox outbreak at Melton Mowbray the schools were kept open and the children could thus be effectively supervised and absentees noted. Dr. S. E. Murray has investigated a series of 77 cases of heart disease and studied their ætiology.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 26th, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 27; scarlet fever, 1961; diphtheria, 929; enteric fever, 76; pneumonia, 764; puerperal fever, 32; cerebro-spinal fever, 6; acute poliomyelitis, 16; acute polio-encephalitis, 1; encephalitis lethargica, 48; dysentery, 3; ophthalmia neonatorum, 103. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 14 from measles, 3 from scarlet fever, 32 from whooping-cough, 41 from influenza, and 24 from diphtheria. There were 173 deaths of children under 2 years from diarrhœa and enteritis, as compared with 220, 219, 230, and 218 in the preceding weeks. In London itself the deaths from diarrhœa and enteritis in children under 2 years numbered 46, as compared with 55, 43, 38, and 40 in the preceding weeks; there were 8 deaths from diphtheria, 4 from whooping-cough, and 5 from influenza.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

G. W. Garde to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

C. F. McLean to be temp. Lt.

MILITIA.

Capt. S. W. Hoyland to be Maj.

TERRITORIAL ARMY.

Lt.-Col. C. H. S. Redmond to be Bt. Col.
Capt. H. F. W. Adams, late R.A.M.C., to be Capt.
Capt. R. C. Aitchison (Res. of Off.) to be Maj. (prov.)
General Hospitals: Lt.-Col. A. H. Gosse to be Bt. Col.

ROYAL AIR FORCE.

Air Vice-Marshal D. Munro, C.B., C.I.E., Director of Medical Services, R.A.F., has been appointed an Honorary Surgeon to the King.

Group Capt. H. V. Wells, C.B.E., has been appointed an Honorary Physician to the King.

Flight Lt. J. C. Osburne is granted a permanent commission in the rank stated.

A. F. Cook is granted a short service commission as a Flying Officer for three years on the active list.

DEATHS IN THE SERVICES.

Major-General Sir Hayward Reader Whitehead, K.C.B., died at Lyndhurst on Sept. 28th, aged 70. A student at Charing Cross Hospital, he qualified with the M.R.C.S. in 1877, and afterwards held appointments both at the institution where he received his medical education and at the Royal Westminster Ophthalmic Hospital. In 1880 he took the F.R.C.S. Eng., and in the same year the L.R.C.P. Edin. Two years later he was awarded the Montefiore Gold Medal at the Army Medical School, Netley, and became a surgeon in the Army Medical Department, reaching the rank of surgeon-major in 1891. He saw service in the Tirah Expedition of 1897–8, and was present at the action at Dargai, the capture of Sampagha and Arhanga passes. He was also with the expedition against the Chamkanni Khel Afridis, and took part in the march through the Bazar Valley (mentioned in dispatches and promoted lieutenant-colonel). From 1891 to 1896 he was assistant professor of military surgery at Netley. In 1905 he was promoted colonel and appointed administrative medical officer in India. In 1908 he served with the Mohmand Expedition as principal medical officer (again mentioned in dispatches), and in the following year he was promoted surgeon-general and appointed Deputy Director of Medical Services, Southern Command. He was transferred to the Eastern Command in 1912. In the second year of the late war he was sent to Malta as Director of Medical Services, and was afterwards appointed to the British Salonika Force. Created C.B. in 1909, he was promoted to K.C.B. in 1917. He also held French, Serbian, and Greek decorations, and was a Knight of Grace of St. John of Jerusalem. He married, in 1893, Evelyn Wynne, daughter of Colonel Cayley, C.M.G., I.M.S.

SIR HAYWARD WHITEHEAD.

THE MOTOR SHOW AT OLYMPIA.

OCT. 9TH TO 17TH.

(BY OUR MOTORING CORRESPONDENT.)

THE CHOICE OF A CAR.

DURING the last six years British cars, especially the small and medium ones, have been developed to an amazing pitch of excellence. They are all in their particular ways first class, and prices appear to have come to rock-bottom and will probably start to rise before the next show. The trouble is to choose. The press particularly interested in motor vehicles issue many bulky show numbers with very complete and accurate buyers' guides ; the *Autocar* has excelled itself in particular. Presuming that the medical man will want a small or middle sized car, preferably covered and absolutely trustworthy ; that he will, perhaps, in the course of his duties overwork it and not attend to it overmuch, and that he will seriously consider the price of the car, these notes will direct him to a few of the many cars that satisfy these conditions. Every single car is superlatively good, and the modern engine develops about twice as much power for its size as the pre-war one. If he wants four-wheel brakes he can generally have them for another £20 or so if they are not fitted as standard ; most cars have low-pressure tyres, and all are fully equipped with excellent starting and lighting sets. Once the medical man buys a car, he may be fairly certain that he need buy nothing and do nothing for six months at least, except pour in fluids and occasionally pump in grease through special nipples with a special gun. The old days of buying indispensable accessories as extras, and then of anxious watching and expensive repairing, are over. Here, then, are a very few possible choices, in ascending order of price.

There are many excellent foreign cars on view as well as our own British makes, but fine as they are, there is none that cannot be matched in our own country.

A Selection of Cars.

Trojan, 10 h.p. Stand 182. Four-seater, £125 with solid tyres and £130 with pneumatic. Wonderful springs and exceptionally simple controls. Very economical running. The saloon cost £158 with pneumatics, but the open model is perfectly waterproof. No electric starter, but has a mechanical device worked from the seat.

Austin, 7 h.p. Stand 211. The smallest British car. Two roomy seats and a capacious boot with an extremely powerful little engine. £149.

Jowett, 7 h.p. Stand 98. Another very powerful miniature, tested fully in the West Riding. The open two-seater is £150, and there is a very good saloon at £200, a new and surprisingly roomy design.

Morris-Cowley, 11·9 h.p. Stand 184. Very sweet to drive, and the starter is exceptionally silent. All Morrisses now have all-weather equipment, shock absorbers, and balloon tyres. Open two-seater £162 10*s*., and £7 10*s*. extra for four-wheel brakes. Coupé £195, saloon £235, both including four-wheel brakes. The Oxford, which is 13·9 h.p. and very luxurious, costs £240 as an open two-seater, £285 as a coupé, and £350 as a saloon, all with four-wheel brakes.

Rover, 9 h.p. Stand 107. Two-seaters £185 and £212 10*s*., saloon £285, including four-wheel brakes. The "super" two-seater costs £220 with four brakes.

Cluley, 10 h.p. Stand 33. Two-seater £225. The all-weather 14 h.p., a recent model, costs £395, and the saloon £475.

Clyno, 11 h.p. Stand 99. This firm makes one of the best motor-cycles in the country, and their cars are equally good. Two-seater £162 10*s*., front brakes £7 10*s*. extra. Saloon, with four-wheel brakes, £265. 13 h.p. two-seater £245, coupé £285, with four-wheel brakes.

Standard, 11 h.p. Stand 106. Exceptionally roomy cars. Coupé £225. 14 h.p., one of the best English two-litre cars. Coupé £365, saloon £450. There are several other kinds of bodies. There is to be a new 12 h.p. chassis at the show, of which no details have been published.

Humber, 9 h.p. Stand 213. Touring £260. 12 h.p. coupé and saloon £555 ; 15 h.p. saloon £860, a splendid car.

Singer, 10 h.p. Stand 181. Two-seater £225, saloon £280, exceptional value. 14 h.p. saloon, £375.

Hillman, 14 h.p. Touring £295, Saloon £345.

Talbot, 8 h.p. Stand 147. Coupé £325. A very fast and sweet-running engine, quite exceptional for its size. 10 h.p. two-seater £350, coupé £415 ; 12 h.p. six-cylinder, wide two-seater, £750.

F.I.A.T. Stand 185. This company has sent a fine batch from their vast factory in Turin, and the little 10 h.p. model which has been so popular in the last two years is better than ever. The coupé costs £365, with four-wheel brakes extra.

Austin, 12 h.p. Stand 211. A beautiful little medium-powered car, four speeds and four-wheel brakes. Coach £395 ; 20 h.p. saloon £650. This is an excellent car of the larger variety at a very low price.

De Dion Bouton. Stand 215. This famous car, which was good even in 1896, worthily represents France. The 10 h.p. coupé costs £395, and the 12 h.p. coupé £610. This make is as fine as anything in the show.

Star, 12 h.p. Stand 136. Touring £365 and £395 ; saloon £445 ; 14 h.p. coupé £525 ; 20 h.p. coupé £700. This firm has made cars from the earliest days, and has six different chassis at this show to choose from, with a large variety of bodies.

Armstrong-Siddeley, 14 h.p. Stand 108. Coupé £425. These are very beautiful cars, by far the cheapest of the real luxury class. The 18 h.p. six-cylinder is one of the most attractive medium-powered cars in the world. The two-seater costs £450 and the coupé £550

Crossley, 14 h.p. Stand 139. All the Crossleys fit four-wheel brakes. The coupé is an ideal doctor's car and costs £540.

Vauxhall, 14 h.p. Stand 135. One of the fastest and best of the two-litre class. There are four-wheel brakes and four speeds on this year's models. Touring £550 and saloon £650 and £750.

Willys-Knight. Stand 150. The Willys six-cylinder and the *Overland* 13·9 h.p. are two fine American-designed machines, the first of which costs £695 and the second £340, both saloon bodies ; they are manufactured in this country.

Sunbeam, 14 h.p. Stand 110. The Sunbeam is one of the very best British cars ; it is designed by Louis Coatelen, and has a wonderful performance. The coupé is £750 and the two-seater £625, with a saloon at £795.

A Few Hints to Novices.

Other models besides those mentioned also have four-wheel brakes and four speeds, but both features are almost universal in the more expensive cars. For the benefit of readers new to motoring a few hints may not be out of place. Low-pressure tyres, now almost universal, increase the smoothness of the running very considerably, and four-wheel brakes add enormously to safety, especially on hills, but they must be kept in proper adjustment. Whether one dislikes gear-changing or not, four speeds are generally more comfortable than three, and certainly save petrol. The most important point to the medical man who drives his own car, next to docility and sweetness of handling, is protection ; this can be judged to a certain extent at sight, but ease of driving needs a road-test. Most coupés keep the wet out, but in some it is difficult to see and signal, and the buyer should sit in the car at the Olympia show and satisfy himself that he can see enough. He should choose a body of grey or brown, which does not show the dirt easily, and should satisfy himself that the controls are well within reach, especially the hand-brake ; inaccessibility is the worst feature of many cars and completely spoils a few excellent ones. He will find a dashboard light useful in open cars ; closed ones usually have an inside lamp. A "strangler," for cutting off the air when starting, is useful on cold nights, but not many British cars have them. And, lastly, when he takes his trial run, let him choose a wet day if possible. Many coupés and saloons that look beautifully snug at Olympia become a perfect shower-bath in wet weather through faulty joints in the windscreen and faulty fitting in the windows.

"Audi alteram partem."

EXPERIMENTAL EPIDEMIOLOGY.

To the Editor of THE LANCET.

SIR,—In your leading article under the above heading in THE LANCET of Oct. 3rd there is one point on which I should wish to offer a comment and an explanation. When I first had the good fortune to engage the interest of Dr. Greenwood in these experiments, some five years ago, it soon became evident that the satisfactory progress of the investigation demanded close coöperation, not only in interpreting the results, but in planning the experiments. Since that time those experiments which were likely to yield data requiring statistical analysis have been devised by Dr. Greenwood and myself, after consideration of the results already obtained, and of the experimental or statistical difficulties likely to be encountered; and the experimental method has, from time to time, been modified as new problems or unforeseen difficulties have presented themselves.

Dr. Greenwood's part of the investigation has, therefore, not consisted merely in applying statistical methods of analysis to results which I have independently obtained; but throughout this part of the work the investigation has been a joint one in the full sense of the word, and the statistical side has been carefully considered in devising the experiments as well as in interpreting the results. It is our firm conviction that full and equal coöperation of this kind is essential if progress is to be made in the investigation of an intrinsically difficult problem.

I am, Sir, yours faithfully,

W. W. C. TOPLEY.

Public Health Laboratory, Manchester, Oct. 2nd, 1925.

TECHNICAL INSTRUCTION IN OPERATIVE SURGERY.

To the Editor of THE LANCET.

SIR,—From what I constantly see I am forced to conclude that in the plethora of subjects which students have nowadays to tackle surgical handicraft is apt to be forgotten, and that operative training is distinctly inferior to that of midwifery in which a number of personal attendances must accompany the application for admission to the final examination. I should like to know what percentage of the candidates for the higher surgical diplomas know how to mop a wound—that is, will apply the sponge with a steady vertical dab instead of a fierce wipe which sweeps away ligatures and causes small unclamped vessels to bleed.

I beg to invite the attention of clinical operators also to avoid teaching their pupils to retain their hands in full pronation when assisting at operation. There is not anything which tempts me more to open my mouth than when the assistant is retracting the edges of wound or applying a ligature to have the whole field obfuscated with his pronated fists, with the result that he barely sees what he is doing and I cannot see anything. It seems somewhat of a farce to set papers for examination containing questions—for example, the dissection and difficulties attending exposure of the pituitary gland, carotid body, or semilunar ganglion—to candidates who do not know how to hold a knife or handle a needle, and if entrusted with the application of a ligature to a pedicle, even money, will make such a violent tug on the second knot as to smash up the whole procedure.

I am quite aware that this burlesque is not, in the majority of instances, due to any personal fault of the unfortunate youth camouflaged with a licence to practise surgery, but to the miserable dog-in-the-manger stunt which gives nothing, and in wanton stupidity, admits of a yearly turn-out of men as qualified surgeons who are absolutely incapable for want of personal technical instruction to perform any operation on any living thing.

I wonder what kind of door or window an embryo carpenter would turn out if he had not served his time, with tools in fist, under the direction of his boss.

I am, Sir, yours faithfully,

Buenos Aires, Sept. 9th, 1925. JOHN O'CONOR.

*** Sir John O'Conor adds in a postscript that his letter was not inspired by anything which Mr. Bernard Shaw has written — or may write. Coming nearer home it cannot have been inspired either by the annotation on "The Surgeon as a Technician" in our issue of Sept. 26th (p. 657) to which it is so highly apposite.—ED. L.

PERSISTENT DIARRHŒA IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—I have found two drugs not mentioned by Dr. de Carle Woodcock useful in the treatment of this very distressing complication. For some time now I have used intramuscular injections (or intravenous, in much weaker dilutions) of calcium chloride in doses of ½–1 gr. at intervals of two or three days. It has certainly some beneficial effect, especially if given in conjunction with large doses of bismuth by the mouth, say 1–2 dr. thrice daily. The action of calcium chloride is very slow, and injections should be continued for two or three weeks before definite results are expected. Persistent diarrhœa in tuberculosis is not always due to specific infection of the bowels; and when there is clinical evidence of fermentative changes in the large gut, dimol in doses of 1 gr. thrice daily is also a very useful adjunct to dietetics and other methods of treatment. This treatment is more effective if a preliminary period of semi-starvation has been prescribed and the tract prepared with a dose of calomel.

Dr. Woodcock raises an interesting point which will have to be settled soon unless pneumothorax therapy is to suffer a set-back. I refer to the connexion between artificial pneumothorax and a supervening diarrhœa. It appears to me that pneumothorax has a tendency to cause (sooner or later) the appearance of another active focus somewhere else in the body, and this tendency is more marked if comparatively high pressures have been used in producing collapse. The intestinal tract, or some other organ, may be the seat of one or two small and comparatively quiescent foci, and by collapsing the lung too effectively or too quickly the patient's system gets an overdose of autotuberculin, resulting in reactivation of these indolent foci.

This is, in my opinion, a real danger in pneumothorax treatment. One is apt to overlook the fact that pulmonary tuberculosis is one manifestation (of many) of a general disease.

I am, Sir, yours faithfully,

FELIX SAVY.

Grampian Sanatorium, Kingussie, Sept. 29th, 1925.

ALTRUISM AND THE "COMMON COLD."

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. J. A. Drake, writes of the thoughtless distribution of the "cold" from person to person. The late Sir William Robertson Nicoll is said to have maintained that "colds, neuralgia, and most other ills arise from the great modern curse of fresh air." The sound of such a voice crying in the wilderness must find an involuntary echo in many conservative hearts beating beneath heavy overcoats to-day; for the curse of fresh air is upon us, and the curse has come to stay. It is true, of course, that although there are few who dare to protest there are many who only accept the inevitable with reservations. Mr. Stephen Leacock, for instance, whilst strongly supporting the use of fresh air, says that after the house has been filled with it the windows and doors should be carefully closed so as not to let any of it escape; properly enclosed it will last for years. In this view he follows Bacon, who remarked in his "History of Life and Death" that: "It is to be observed that air accustomed to the body doth less prey on it, than new air, and often changed." But the fashion of the day is to favour fresh air in and out of season and in every place except the secret places of the home.

It is supposed by many that this retrogressive movement back to Nature will eliminate half the minor diseases of the cities, and in particular it is claimed that the common cold is doomed as soon as it is threatened with an open window. If it were to receive, they say, another name more in keeping with its ætiology, such as a "warm" or a "stuffy," it would never have an opportunity to attack anyone again. But here they do not convince the majority of reasonable people, who think that an open window threatens the patient more than his disease, and who know perfectly well that whether you call it common-or-garden or common-or-drawing-room, there is no doubt of the trouble being a *cold*.

It is, of course, an ingenious idea that the sensation of chill invariably associated with the onset is due to the first working of the disease in the system; and such no doubt is the explanation of the general experience which gave the name to the complaint. But it is too much to say that cold is not and cannot be an ætiological factor. There are certain people who react astonishingly rapidly to the chilling of their feet, by the immediate development of profuse rhinorrhœa. This may be a purely nervous disorder, but the fact remains that it is only necessary for them to remove their shoes and walk about on a cold floor for a few minutes in order to work the oracle, and if medical opinion cannot accept any mysterious connexion between the nose and the feet, apart from their common faculty of running, it must at least consider whether local improperly compensated chill does not play some part in stirring up nasal infection. Such a defence is the last ditch of the diehard; but even a proof of the connexion between cold and colds cannot save him from those who prefer to put the hardness into living.

It was long ago observed that whereas the English muffled themselves to the eyes when out of doors and permitted a freezing blast throughout their houses, the French, whilst keeping very warm indoors, took the air outside their houses in the scantiest garb. Each of these habits is as reasonable as it appears foolish. When man originally adopted clothing it was intended to permit his exposure to colder climates, and so far it was successful; but since then it has been used to dull the activities of the skin and the race has simply been geared up to warmer surroundings. Any system which encourages the exposure of healthy persons to extremes of temperature, and relegates clothing and housing to their proper place as mere supplements, is increasing the human efficiency. Especially it reduces susceptibility to chill, and the use of cold baths and the habit of wearing as few clothes as possible in all weathers is most likely to produce a healthy skin which will laugh at exposure to draughts. Such a régime is applicable only to those who react properly to it, and for those who suffer from constitutional disease, or for the aged, a protected life is obviously desirable. "And therefore," said Bacon, "poor people who live always within the smell of the same chimney and change not their seats are commonly longest lived, notwithstanding to other operations, especially for them whose spirits are not altogether dull, we judge change of air to be very profitable." Another class for whom the panacea of exposure proves ineffective in preventing colds is that enormous body of persons with nasal abnormalities. How many medical men hide a deflected septum beneath a smiling face? Reflection on such organic aspects of the common cold leads to consideration of infection. The only change in nomenclature which would at present find favour with the man in the street would be a change from active to passive mood. He considers himself caught, rather than catching. Agreeing with the ancient saying that chronic diseases are brought upon a man by himself but acute diseases are an act of God, he shifts the responsibility for his illness from himself on to the micrococci. And, however much the cultivation of general resistance to cold may be in fashion, it remains true that massive infection or foreign infection will lay low the Arctic explorer or the returning holiday-maker whose resistance may be supposed good. How then can the average man, relying pathetically on a cold bath and an evening stroll without an overcoat, hope to prevail against sudden proximity with a virulent strain of organisms recently developed in another suburb? It seems that everyone likes to get the greatest possible pleasure from misfortune. Seized by a cold some people concentrate on the physical compensations of bed, hot whisky, and sympathy; but others prefer moral satisfaction and carry on bravely with conscious pride. This is more subtle, but far more scandalous, for only too often the path of glory leads but to the grave—and the unfortunate thing is that it is usually someone else's grave. If everyday life must throughout the winter be cursed with such members of society let them at least be segregated. Let them travel only in railway carriages intended for the purpose and clearly labelled "colds," and there let them close the windows and there let them create an emulsion of pride and micrococci to their heart's content.

I am, Sir, yours faithfully,

Oct. 1st, 1925. F.R.C.S.

A SURGICAL COINCIDENCE.

To the Editor of The Lancet.

Sir,—The occurrence of the same surgical emergency twice in a patient must be very rare. A. M. Z., an Egyptian labourer, aged 40, was brought to me in January, 1923, suffering from acute intestinal obstruction. On examination I remarked a sausage-shaped swelling plainly visible under the abdominal wall. I operated under stovaine anæsthesia and reduced a volvulus of the sigmoid flexure, the patient making an uneventful recovery in 12 days. In August, 1925, a man suffering from abdominal pain came to me, and I was at once struck by something vaguely familiar about the look of his abdomen. It was the same sausage-shaped swelling in my same friend of two and a half years before. I operated under stovaine again, and this time I put some "reefs" into his sigmoid mesentery, so I hope his accident will not occur again. He made another uneventful recovery and left hospital in 13 days.

I am, Sir, yours faithfully,

H. E. S. Stiven,

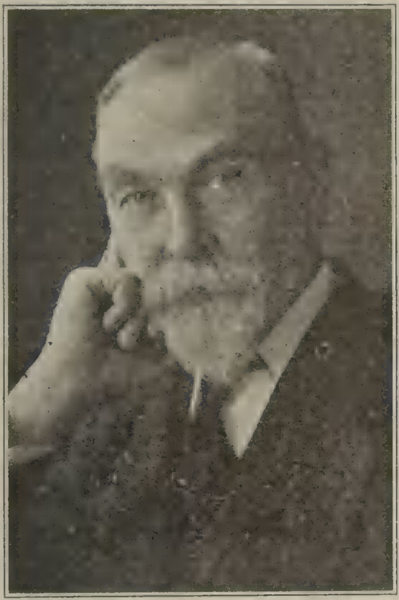
P.M.O., Egyptian Government Hospital,
Sept. 10th, 1925. Port Said.

Vaccination and Compulsion in Ireland.—Our Dublin correspondent writes: "The vaccination laws in Ireland are compulsory, and no loophole is provided for the conscientious objector. As a result vaccination is, on the whole, fairly thorough, and there has been no outbreak of small-pox in the country for a great many years. During the disturbed period four or five years ago vaccination, however, fell into partial neglect, and when the present Department of Local Government and Public Health came into power there was much leeway to be made up. In most areas this has been done without trouble or opposition, but in the south-east corner of the country, County Wexford, and neighbouring areas, there has for long been a fairly strong antivaccinationist movement, and opposition in that district has been general. The Department of Local Government has done its best to persuade the county health board of Wexford to enforce the law in regard to vaccination, but has failed, and recently the board was informed that steps would be taken by mandamus unless the law was obeyed. The board was still recalcitrant, and it is expected that the department will apply for a mandamus as soon as the courts sit."

Obituary.

JAMES NIVEN, M.A., LL.D. ABERD., M.A., M.B. CAMB.

BY the death, on Sept. 30th, of Dr. J. Niven, late medical officer of health for Manchester, the medical profession is deprived of a member of outstanding character and ability.



DR JAMES NIVEN.
[Photograph by Lafayette.

James Niven was born in 1851, and after graduating in Arts at Aberdeen he went to Cambridge, where he had a distinguished career as a mathematician. He was eighth wrangler in 1874 and was afterwards elected to a Fellowship at Queen's College; but although his original intention was to study engineering, he went on from Cambridge to St. Thomas's Hospital, and after taking his M.B. in 1880 held an appointment under the Metropolitan Asylums Board. He then went to Manchester and practised privately for four years in a southern suburb. In 1886 he was appointed medical officer of health for Oldham, and in 1894 the sphere of his influence was again widened when he succeeded Dr. John Tatham in the Manchester office. In the 28 years that followed he proved himself one of the greatest of medical officers of health, and one of the most useful public servants that Manchester has ever had. Apart from routine work he carried through many important reforms. In conjunction with the late Prof. S. Delépine he was able to bring about immense improvement in the city's milk-supply; considerable progress was made against tuberculosis, and great strides were made by Manchester in sanitation. It was largely due to his efforts that the death-rate fell from 24·26 per 1000 in the year before his appointment to 13·82 in 1921. His great achievements were made possible by his intense zeal, his patience and perseverance in attention to detail, and his courage in maintaining his opinions when he was satisfied that they rested on a basis of ascertained fact. There were others equally, or even more, successful in the everyday work of administration, but there was none who explored or proved so thoroughly the foundations of public health, or who pointed out so surely or so wisely the lines along which sanitary reform must proceed. No department of health practice escaped his scrutiny, and each in turn was made the subject of careful study; on each he left the impress of his critical and constructive wisdom. He was essentially a realist; he never lost sight of the economic aspect of health work, nor forgot that the chief end and justification of expenditure is the production of healthier, happier, more efficient citizens. Dr. Niven will be remembered for his insistence upon housing reform, for his revision of existing methods of dealing with infectious disease and the machinery of disinfection, and for his valuable interest in tuberculosis. He was the first to advocate notification, and based his useful reports on a voluntary notification scheme.

A record of his work, entitled "Observations on the History of Public Health Effort in Manchester," was published in 1923. His other contributions to medical literature were numerous, and his advice was rightly in request at the Ministry of Health, and by his colleagues in the health service. In giving evidence he was always terse and convincing. He was president of the Epidemiological Section of the Royal Society of Medicine, examiner in sanitary science at Cambridge, and lecturer in public health at Manchester University. For his services to preventive medicine he was given medals by the Royal Institute of Public Health and other bodies, and on his retirement from active work at Manchester in 1922, when he passed the age limit, he was publicly thanked by the city.

A former assistant writes: "As a man Niven was possessed of a singularly noble and winning character. One recalls especially his courage and independence, his tireless industry, his unselfishness, his intolerance of sham, and his love of children. Generous in his estimate of the work of others, he was a tireless critic of his own shortcomings. He had a great capacity for inspiring affection and devotion in his staff, and to those of us who were privileged to be so numbered there remains the enduring memory of a kind friend and 'true and very gentle knight.'"

Dr. Niven's somewhat shy and reticent manner hid a personal character that was generous and kindly. His life was one of continuous and unsparing effort in the public cause. Himself a remarkable man, he was a member of a remarkable family. His three brothers were also wranglers at Cambridge; the eldest was Sir William Niven, who was Director of Studies at Greenwich Naval College; and another was Charles Niven, first wrangler in 1867, who became professor of natural philosophy at Aberdeen. Dr. Niven's wife died 12 years ago, and he leaves three daughters.

ALAN REEVE MANBY, M.D. DURH., F.R.C.S. ENG.,

PHYSICIAN EXTRAORDINARY TO THE KING AND QUEEN ALEXANDRA.

Alan Reeve Manby was born in 1848, the son of Dr. Frederic Manby who practised at East Rudham, in Norfolk, and to whose practice he succeeded. He was educated at Epsom College and at Guy's Hospital, where he filled, among other posts after qualification, that of obstetric resident. Almost immediately he joined his father in a practice which had been carried on previously by his grandfather, and from the first he showed the qualities which made him a success in general practice. In 1885 he was appointed surgeon apothecary to the household at Sandringham, where the Prince of Wales, afterwards Edward VII., was often in residence, leading the life of a county gentleman. On the accession of Edward VII. Manby was appointed physician extraordinary, a position which he afterwards held in respect of the present King and of Queen Alexandra. In 1901 he went in attendance on the Prince and Princess of Wales, the present King and Queen, during their Colonial tour, when he received the M.V.O. Two years later he was knighted, and in 1918 promoted K.C.V.O. He was also a Knight Commander of the Order of Dannebrog of Denmark. His intimate relations with the Court were never allowed to interfere either with his practice or with his interest in professional and local affairs. He had a considerable obstetric practice and was at different times chairman of the Norfolk and Norwich Medico-Chirurgical Society, and president of the East Anglian branch of the B.M.A. He was the author of short but practical clinical contributions to THE LANCET and other medical journals, and devised some improvements in several surgical instruments.

He married in 1876 Charlotte, daughter of the late Edmund Farrer, of Petygards, Swaffham, by whom he had one son, Mr. Percy Manby, the Judicial Commissioner of the Malay States, and one daughter, the wife of Dr. F. J. Willans, who succeeded his father-in-law as surgeon apothecary to Queen Alexandra and the household at Sandringham.

EDMUND LANGLEY HUNT, C.M.G., L.R.C.P.I.

Dr. Langley Hunt, whose death took place in London on Sept. 30th, was superintending medical officer of Jamaica and was home on leave when he was taken ill. Born in 1868, the second son of the late E. Langley Hunt, of Co. Limerick, he qualified at the Irish Royal Colleges in 1894 and became a civil surgeon with the South African Field Force (1899–1902), part of his service being on the personal staff of the Commander-in-Chief. He was twice mentioned in despatches (two medals, six clasps) and was awarded the C.M.G. in 1902. Later he was employed in the Anglo-German Boundary Commission to Lake Chad, when he received the thanks of the German Government and the Royal Order of the Crown of Prussia (third class). He was appointed to the West African Medical Staff in February, 1905, and did notable work at the time of the outbreak of plague at Accra in 1908. In 1912 he was transferred to Ceylon as inspecting medical officer, becoming principal officer two years later. He was transferred on promotion to Jamaica as superintending medical officer in 1919. Dr. Hunt leaves a widow and three sons.

WILLIAM MORRISTON DAVIES, M.D. EDIN.

WE regret to note the death on Sept. 23rd, after a short illness at Bournemouth, of Dr. William Morriston Davies at the age of 83 years. Dr. Davies was a native of Glamorganshire and spoke Welsh only until he was 16 years old. He graduated at Edinburgh in 1873 and started practice the following year in Huntingdon with Dr. Michael Foster, father of the famous physiologist of the same name. After six years he moved to London, where he practised at 55, Gordon-square, amidst an ever-increasing circle of patients and friends, until his retirement in his sixty-ninth year to the Manor House, Stoke Poges. To his professional duties and to his private life Dr. Davies brought an earnestness and an intuition which gained him the affection of his patients and the esteem of the physicians and surgeons he called to his aid. In his private life he was an enthusiastic collector of old furniture, silver, and mezzotints, and devoted all the time he could spare to travel and sightseeing, in the course of which he acquired an intimate knowledge of the architectural beauties in the cities of England and Europe. A member of the Alpine Club, he was a keen climber, his wife accompanying him in most of his ascents. Dr. Davies was the possessor of an acute power of observation and an ability to retain a clear and correct memory of all that he saw and read. He was a lover of the beautiful both in art and nature, and with his strong personality acquired a host of friends whom he never failed to instil with a similar enthusiasm.

WILLIAM RONALD KIRKNESS, M.R.C.S. ENG.

Dr. W. R. Kirkness, who died on Sept. 19th at Pembury, Tunbridge Wells, at the age of 50, was a son of the late Captain W. Kirkness, of Falmouth. Born at Wimbledon in 1875, educated at Rossall and King's College School, and then deciding to follow the profession of his grandfathers, Dr. Kirkness, of Truro, and Dr. Soltau, of Plymouth, he entered King's College Hospital and became qualified M.R.C.S., L.R.C.P. in 1904. After holding appointments at Wolverhampton, Westminster, West Herts, Children's Hospital at Hackney, and Mount Vernon Hospital for Consumption, he took up general practice at Portsmouth where, in addition to his own work, he acted during the war as civil medical officer with 13th Battalion R.F.A., and R.A.O.C., R.A.S.C., and R.E. When the war ended his health began to deteriorate, so, greatly to the regret of his colleagues and patients at Portsmouth, Dr. Kirkness disposed of his practice and took a smaller one at Pembury, Tunbridge Wells, where he held the appointments of medical superintendent of Tonbridge Union Infirmary and Hospital, medical officer to the Capel Isolation Hospital, and district medical officer of the Tonbridge Union. During the six years he was at Pembury he gained the confidence of a large clientèle and was always willing to assist his fellow practitioners. A chill caught during the course of his duties brought on an attack of pleurisy and double pneumonia which proved fatal despite every attention. His death has cast a gloom over a district where he was universally liked.

Dr. Kirkness leaves a widow, a son, and a daughter, the former a student at Epsom College.

Medical News.

HOSPITAL DINNERS.—A large gathering of old students of *St. Bartholomew's Hospital* sat down in the Great Hall of the hospital on the evening of Oct. 1st, Mr. John Adams, F.R.C.S., occupying the chair. In proposing the health of the Hospital and of the Medical College, the Chairman contrasted the present body of 700 students, 80 per cent. of them University men, with the 223 students in attendance when he entered the hospital in 1868. Bart.'s men had, he said, won during the past year the gold medals at the M.D., M.S., and M.B., B.S. examinations of London University. Sir William Lawrence responded for the hospital in the regretted absence of Lord Stanmore through illness. Plans for new hospital buildings had, he said, at last been drawn up, to be submitted to the Governors next month. There would be 740 beds on the present site, with an additional paying-block of 80 to 100 beds. The Great Hall was to remain as it now was. Mr. W. McAdam Eccles, in replying for the College, spoke of the four medical professorships of London University within the school and of his wish to see all these chairs adequately endowed, and anatomy housed as well as physiology, physics, and pharmacology at present were. During the last summer they had been through another very successful post-graduate course for old hospital men. Sir Anthony Bowlby, who received an ovation, proposed the Health of the Guests, amongst whom were Sir John Bland-Sutton, Sir Archibald Garrod, Surgeon Vice-Admiral J. Chambers, Lieut.-General Sir William Leishman, and Air Commodore D. Munro. Sir John Bland-Sutton responded. The Chairman's Health was proposed by Dr. W. Langdon-Brown and warmly honoured. After dinner there was the usual adjournment for conversation to the School Library.

Charing Cross Hospital held its annual dinner on Oct. 5th in the Adelaide Gallery at Gatti's Restaurant. Dr. W. J. Fenton, the dean, took the chair. The loyal toast was described on the list as "Our Most Illustrious Doctor, His Majesty the King," and there were no other toasts and no speeches whatever, in spite of a vociferous demand that Sir Herbert Waterhouse should play the raconteur. After dinner Mr. John Goss, with the Cathedral Quartette, sang some really delightful songs and chanties. For the arrangement of some of them, including the favourite war song "And if I die, don't bury me at all," the pianist (Mr. Hubert Foss) was responsible, and several had been arranged or composed by Mr. S. Taylor Harris, a student at the hospital. His very spirited ditty about a pirate sprang into immediate local popularity which should become widespread.

The annual dinner of past and present students of *St. George's Hospital* was held on Oct. 1st at the Hyde Park Hotel, Mr. F. Ashton Warner, F.R.C.S., in the chair, when 160 alumni of the hospital attended, nearly a record gathering. Diners were grouped at small tables and speeches were cut down to a minimum. After the loyal toast, Mr. W. C. Bridgeman, First Lord of the Admiralty, proposed the Hospital and Medical School. He contrasted the difficulties of the medical profession with those of politicians, inferring that, if anything, the doctor had rather the better of it. Some of the general practitioners present appeared to be not quite sure that this was really the case. Dr. James Torrens, Dean of the Medical School, in responding to the toast spoke hopefully of the future of the School, and announced that the entry this year was the highest since 1899. Sir Humphry Rolleston and Sir George Turner were toasted by the company and briefly responded. The success of the evening was largely due to the work of the secretaries, Mr. G. A. Ewart, Dr. Bellingham-Smith and Dr. Gilbert Orme.

The annual dinner of the old students of the *London Hospital* was held on Oct. 1st at the Trocadero Restaurant. The chair was taken by Sir Hugh Rigby, senior surgeon to the hospital, and nearly 200 old students were present. The Chairman congratulated the hospital on its great and increasing prosperity. The school, he said, showed no signs of birth control, and though labour might sometimes be difficult her sons were more numerous than ever, and as devoted as ever to the mother who gave them birth. Financially, thanks to the wizard hand of Lord Knutsford, the hospital had never been more prosperous, and the appreciation which laymen felt for its work was well illustrated by the generous gifts of £10,000 each from Lord Bearsted and Mr. Barron for a clinical theatre and a pathological laboratory respectively, as well as by the latest gift of £50,000 from an anonymous donor for research. With the development of the medical unit, of the system of annex hospitals, and of changes in the organisation of the receiving room and the out-patient department, many old traditions were passing away, but he hoped that nothing would ever be done to disturb the responsibility with which the residents were entrusted, to which we so largely owed the splendid type of practitioner whom everyone associated with the hall-mark of the London Hospital. Team-work was the great demand of the present day, but nowhere could be found a more united or a more devoted team than the past and present students of the hospital which he and his audience were proud to own as their mother.

The annual dinner of *St. Mary's Hospital Medical School* was held on Oct. 5th in the Connaught Rooms, Mr. Leslie Paton in the chair. A large gathering of St. Mary's men and women and their guests was present. In proposing the toast of the school, the chairman said that a teaching hospital filled three important functions: first, the healing of patients; second, research; and third, the teaching of students. It was the third function that was the most vital; no research work was so good as that which was constantly clarified by teaching it to others, and clinical work by being constantly and critically watched by students was benefited greatly. Mr. Paton then paid a feeling tribute to the late Sir Anderson Critchett. Mr. A. R. Prideaux, chairman of the Hospital Board, spoke in reply of the hospital's finances. The past year showed a deficit of £3000, but the prospects for the coming year were more encouraging. A gift of £2000 had recently been received for the purchase of radium, and a further £2000 had been given anonymously. The National Sporting Club had contributed over £6000 annually as the proceeds of boxing tournaments. Dr. C. M. Wilson, Dean of the School, who also replied, explained how the expenditure of the school had increased out of all proportion to the pre-war income from students' fees. The prestige of the school to-day was higher than it had ever been, and he had a very sensitive barometer for estimating that prestige. On the athletic side also the school record was a brilliant one. The health of the chairman was proposed in a humorous speech by Dr. R. H. Miller, and Mr. Paton replied.

The annual dinner of the past and present students of the *Middlesex Hospital* was held at the New Criterion Restaurant at 7.30 P.M. on Oct. 1st. The chair was occupied by Sir Arnold Lawson, ophthalmic surgeon to the hospital. There was a large gathering of the past and present students and their friends, numbering in all about 250. Among the guests were the Hon. Sir Arthur Lawley, Prof. E. A. Gardner, and the Mayor of Marylebone. After the usual loyal toasts, the Chairman proposed prosperity to the Middlesex Hospital and its medical school. He referred to the arrangements being made to carry on the work of the hospital during the rebuilding, to the efforts in train to raise the necessary funds, and to the satisfactory response so far obtained, thanks to the help afforded by the various agencies concerned, including the press, the various committees, the students, and the nurses. He announced that the efforts of the past students and present together so far had realised £4000. Mr. Reginald Beddington replied on behalf of the board. He alluded to the arrangements made to supply accommodation for patients during the rebuilding and stated that they would not involve the loss of a single bed. Mr. Eric Pearce Gould, the Dean, replied for the school. He paid a generous tribute to the work of his predecessor, Mr. A. E. Webb-Johnson. He referred with great satisfaction to the developments in the school during the past year, notably to the appointment of Prof. E. C. Dodds to the University chair of biochemistry, and to the generous gift of a large sum for the study of laryngology and otology from Mr. T. Ferens. Dr. T. L. Hardy, of Birmingham, replied on behalf of the past students, and referred with pride to the reputation of his old school. Mr. E. W. Riches, the Broderip Scholar, made a witty and amusing speech in replying for the present students. The toast of the Guests was proposed by Mr. Sampson Handley, and responded to by Sir Arthur Lawley and Prof. Gardner. The toast of the Chairman was proposed by Dr. R. A. Young. Sir Arnold Lawson replied, expressing his gratification at the large attendance.

The annual dinner of past and present students of the *Westminster Hospital* was held on Oct. 1st in Oddenino's Restaurant, Regent-street. Dr. H. B. Brackenbury was in the chair. The toast of Westminster Hospital students, past and present, was given by the Chairman, who said that he thought of all those who were there that evening as present students; past students could only refer to those who had passed away. A student of Westminster Hospital remained a student throughout his life, still learning from the work which went on there. He had, he said, in special memory many who had now passed away after doing excellent work, and also the actual students of to-day who were faced with new and difficult problems. The toast was responded to by Dr. Charles Roper on behalf of the old students, and Mr. R. G. Hodges made a happy and skilful speech for the younger generation. Mr. E. Rock Carling proposed the toast of the Chairman. For the remainder of the evening the ratio of songs to speeches was judiciously balanced, and the function was a very enjoyable one.

Chelsea Clinical Society.—The annual dinner of this society will be held at the Café Royal, Regent-street, on Tuesday, Oct. 20th, at 7 for 7.30 P.M. Dr. P. Seymour Price, president, will be in the chair.

University College Hospital Dinner.—The annual dinner of past and present students of University College Hospital will be held at the Hotel Cecil, Strand, on Friday, Oct. 16th, at 7.30 P.M., with Dr. Herbert Spencer in the chair.

Prince of Wales's General Hospital: Reunion Association.—The annual dinner usually held during "motor week" will this year take place early in November. Members will be notified in due course of the actual date and place.

Harveian Society of London.—A clinical meeting of the Society will be held at the Hospital for Epilepsy and Nerve Diseases, Maida Vale, on Thursday, Oct. 15th, at 4.30 P.M.

Society of Superintendents of Tuberculosis Institutions.—A meeting of the Society will be held at 122, Harley-street, on Monday, Oct. 19th, at 3 P.M. Papers will be read by Dr. J. W. Linnell on Some Reflections on the Diagnosis and Treatment of Tuberculosis, and by Dr. F. R. Walters on Needs and Indications in Pulmonary Tuberculosis.

People's League of Health.—The first of the Sims Woodhead series of constructive educational health lectures under the auspices of the League will be delivered to-day (Friday) by Prof. Pembrey on Elementary Anatomy and Physiology in the Fyvie Hall, Regent-street Polytechnic, Regent-street, W., at 6 P.M.

Medical Defence Union.—At a meeting of the Council of the Medical Defence Union, Ltd., held on Oct. 1st, Sir Herbert Waterhouse, consulting surgeon to Charing Cross Hospital, was appointed president of the Union for the ensuing year, in room of Mr. W. G. Spencer, retired.

Royal Society of Arts.—On Monday, Nov. 9th, a conference will be held at the house of the society, John-street, Adelphi, W.C., on How the Midwife can Help in the Reduction of Maternal and Infantile Mortality. The chair will be taken by Sir Francis Champneys, Bt. The speakers will include Dr. John S. Fairbairn, Miss E. M. Doubleday, Lieut.-Colonel Fremantle, and Sir John Robertson.

Medical Society of London.—The programme for the first half of the session 1925–26 opens with the annual general meeting at the House of the Society, 11, Chandos-street, W., on Monday, Oct. 12th, at 8 P.M. At 8.30 P.M. Sir Holburt J. Waring will deliver his presidential address on Osteopathy, Chiropractic, and Medicine. The following meetings will also be held on Mondays, at 8.30 P.M.: Oct. 26th, clinical evening, exhibition of cases and skiagrams; Nov. 9th, discussion on Obscure Pyrexia in Childhood, to be introduced by Dr. Robert Hutchison; Nov. 23rd, clinical evening; Dec. 14th, discussion on the Treatment of Genito-Urinary Tuberculosis, to be introduced by Mr. Cyril A. R. Nitch.—The Lettsomian Lectures on the Principles of Treatment in Relation to Diseases of the Nervous System will be delivered on Monday, Feb. 15th, Wednesday, Feb. 24th, and Monday, March 15th, 1926, by Dr. E. Farquhar Buzzard.—The annual oration will be delivered in May, 1926, by Sir Berkeley Moynihan. —The Lloyd Roberts Lecture on Man's Structural Defects will be given on Monday, Nov. 16th, at 5.30 P.M., at the Royal Society of Medicine by Sir Arthur Keith.

Dr. Addison has been adopted as prospective Labour candidate for the Swindon Parliamentary Division.

THE annual service of the Guild of St. Luke, Evangelist and Physician, will be held on St. Luke's Day, Oct. 18th, at 6.30 P.M., at Westminster Abbey.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the seventieth session will be held to-day (Friday) in the Board Room of the Miller General Hospital, Greenwich, S.E., at 8.45 P.M., when the officers and council for the ensuing year will be elected. Dr. H. S. Knight, the President, will occupy the chair. Clinical cases will be shown by several members.

UNIVERSITY OF BRISTOL.—In a special Final Examination for the degrees of M.B., Ch.B. (Part II.), held recently, the following candidates were successful in public health only (completing examination): Charles T. Hyatt and Hubert J. Satchwell.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the monthly meeting of the Faculty, held on Oct. 5th, George Lynn Pillans, M.C., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg., was admitted, after examination, as a Fellow of Faculty.

MANCHESTER BABIES' HOSPITAL.—The new buildings will be opened by the Earl of Derby on Monday, Oct. 19th, at 3 P.M.

THE LATE DR. WILLIAM SANG.—Dr. Sang, who died recently at his residence in Dundee, at the age of 80 years, was a native of that city. He retired from practice only three years ago owing to ill-health. He graduated at Edinburgh University in medicine and surgery in 1871, proceeding to the M.D. degree in 1884. He had contributed several papers on medical subjects to medical journals, among them being one, in 1891, on a case of accidental poisoning by Epsom salts.

ROYAL INSTITUTE OF PUBLIC HEALTH.—A course of lectures on Preventable Diseases will be delivered in the Lecture Hall of the Institute, 37, Russell-square, London, W.C. 1, on Wednesdays, Oct. 14th to Dec. 16th, at 4 P.M. The first lecture will be delivered (on Oct. 14th) by Colonel S. Lyle Cummins on the Prevention and Arrest of Tuberculosis. Lieut.-Colonel Cuthbert James will be in the chair. These lectures, whilst intended primarily for the Fellows and members of the Institute, all others, men and women interested in medico-sociological problems, are cordially invited to attend. The Harben lectures will be given by Prof. J. C. G. Ledingham on Current Problems in Bacteriology and Immunology, and their bearing on Public Health Effort, on Dec. 9th, 10th, and 11th, at 5 P.M. Copies of the syllabus may be obtained from Dr. E. W. Hope and Dr. T. N. Kelynack, hon. secretaries, at the Institute.

SURGICAL INSTRUMENT MANUFACTURERS' ASSOCIATION, INC.—The annual dinner of this Association, which is affiliated to the National Union of Manufacturers, was held on Friday, Oct. 2nd, at the Holborn Restaurant, Kingsway, Mr. Ernest W. Mayer being in the chair. The toast of the Association was proposed by Mr. H. E. Curtis, who gave a short résumé of its history. The Association, he said, was a war-time product, due to the thought of Mr. Edwin Arnold, who, in 1917, brought, by its foundation, the members of the surgical instrument trade together. The first President was Mr. Down under whose able guidance the Association had flourished exceedingly. Mr. Godfrey Cheesman, general secretary of the National Union of Manufacturers and former secretary of the Association, in response to the toast, said that it should be incumbent on public spending bodies to buy British goods, and gave some instances where certain communities had transgressed in this respect. He referred to the spirit of amity and coöperation that existed in the Association, and salted his remarks with several amusing anecdotes. Colonel A. Young, C.B.E., proposed the Guests in a humorous speech, and Sir W. Arbuthnot Lane, in reply, paid a tribute to the superiority of British surgical instruments. "Surgeons don't realise," he said, "how much they owe to the surgical instrument makers." "The Chairman" was proposed by Mr. W. T. R. Beckett, and Mr. Mayer replied. During the evening a pleasant programme of music and song was dispensed by Miss Ethel Kemish, Miss Blanche Gaston Murray, Mr. George Webber, and Mr. Hector Gordon.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Oct. 12th.

WAR: at 5 P.M.
Presidential Address:
Lt.-Gen. Sir William Leishman (Director-General, A.M.S.): Research in the Medical Services.

Tuesday, Oct. 13th.

THERAPEUTICS AND PHARMACOLOGY: at 5 P.M.
Discussion on
Some Difficulties in the Use of Insulin, to be opened by Dr. George Graham (President).
The following have also promised to contribute:
Prof. H. MacLean, Dr. R. D. Lawrence, Dr. E. P. Poulton, Dr. G. A. Harrison.

Thursday, Oct. 15th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Cases:
Dr. J. H. Sequeira: (1) A Private Case for Diagnosis. (2) Kaposi's Multiple Pigment Sarcoma.
Dr. A. C. Roxburgh: Lupus Erythematosus.
Other cases will be shown.

Friday, Oct. 16th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.
Presidential Address:
Dr. Alastair MacGregor: Then and Now.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Oct. 12th.—8 P.M., Annual General Meeting. 8.30 P.M., Ordinary Meeting. The President's address on Osteopathy, Chiropractic, and Medicine, by Sir Holburt J. Waring, to be followed by a discussion.

BIOCHEMICAL SOCIETY (Biochemical Department, Cambridge).

SATURDAY, Oct. 10th.—3 P.M., Dorothy Needham and J. Needham: The Micro-Injection of pH and rH Indicators. G. S. Lund and C. G. L. Wolf: The Fermentable Sugar in Blood. F. G. Hopkins: An Oxidation of Proteins promoted by Glutathione. Mrs. H. J. Coombs and Marjory Stephenson: The Gravimetric Estimation of Bacterial Growth. L. J. Harris: Extension of the Principles of Acidimetry. Application to Certain Biochemical Problems: (*a*) Analysis of Amino-acid Mixtures; (*b*) Volumetric Estimation of Casein and other Proteins: (*c*) The Rationale and Prediction of Protein Behaviour; (*d*) Polypeptides; (*e*) Insulin. H. F. Holden: The Estimation of Glucose. C. S. Hicks: The Effect of a Tryptophane-Free Diet on the Thyroid Gland of the Rat, with Studies in Heat Production. C. S. Hicks: The Ultra-Violet Absorption Spectrum of Acetyl-Thyroxin. C. S. Hicks and M. L. Mitchell: A Preliminary Report of the Study of Induced Polyuria in Rats. H. W. Dudley and W. V. Thorpe: A Synthesis of N-methylputrescine and of Putrescine. J. B. S. Haldane: The Effect of Diuresis on Purin Metabolism. H. J. Channon and J. C. Drummond: Feeding Experiments with Spinacene.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Oct. 15th.—8.15 P.M., Opening Meeting of Session. Dr. Andrew Balfour, C.B., C.M.G., President: Inaugural Address on Some of Our Pioneers, illustrated by lantern slides. The meeting will be preceded at 7.45 P.M. by an exhibition of some interesting works on tropical medicine and hygiene dating from the middle of the eighteenth century onwards.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 12th, to SATURDAY, Oct. 17th.—COMBINED CHILDREN'S COURSE, Paddington Green, Victoria Hospitals, and Children's Clinic. Morning and afternoon sessions.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road. Special course in Laryngology, Rhinology, and Otology. Clinical course and Operative Surgery course, of which one or both may be taken.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens. Tuesday and Thursday, clinical demonstration by Dr. G. C. Low and Dr. P. Manson-Bahr at 2 P.M. The subjects considered will be the more important diseases of tropical countries, illustrated by cases in hospital.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: OCTOBER-NOVEMBER, 1925.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, Oct. 12th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Paraplegia and Its Treatment: Dr. Riddoch.

TUESDAY, Oct. 13th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Epilepsy: Dr. Adie.

THURSDAY, Oct. 15th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Syringomyelia: Dr. Martin.

FRIDAY, Oct. 16th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Acoustic Nerve Tumours: Mr. Sargent.

The fee for the Course, including Pathology lectures, is £5 5*s*. For those who hold Perpetual Tickets the fee is £3 3*s*.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.

THURSDAY, Oct. 15th.—12 noon, Neuroglial Reaction: Dr. J. G. Greenfield.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.

MONDAY, Oct. 12th.—12 noon, (*a*) The Peripheral Nervous System, (*b*) Spinal Cord: Dr. J. L. Birley.

Dr. H. J. Macbride will give a COURSE of EIGHT CLINICAL DEMONSTRATIONS, chiefly on METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2*s*. (commencing Tuesday, Oct. 20th).

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 o'clock, or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. GREENFIELD, Dean of Medical School.

UNIVERSITY COLLEGE, London.

MONDAY, Oct. 12th.—5 P.M., Mr. R. J. Lythgoe: The Physiology of Hearing and Vision (first of a course of eight public lectures).

WEDNESDAY.—5 P.M., Second lecture.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

TUESDAY, Oct. 13th.—5 P.M., Dr. A. C. Roxburgh: Eruptions due to Physical Causes.

THURSDAY.—5 P.M., Dr. R. F. Fagan: Pathological Demonstration.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Oct. 14th.—4 P.M., Colonel S. Lyle Cummins: The Prevention and Arrest of Tuberculosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

THURSDAY, Oct. 15th.—3 P.M., Mr. Norman Fleming: Demonstration of Fundus Cases. 4.30 P.M., Mr. Aubrey Goodwin: Lecture, Treatment of Vaginal Discharges.

Daily: In-patient and Out-patient Clinics in General and Special Departments, Operations, &c.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Oct. 15th.—4 P.M., Mr. Fairbank: Spinal Caries.

ANCOATS HOSPITAL POST-GRADUATE LECTURES.

THURSDAY, Oct. 15th.—4.15 P.M., Mr. E. E. Hughes: The Significance of Urinary Symptoms.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY. Oct. 13th.—4.15 P.M., Mr. D. L. Sewell: Chronic Empyema of the Maxillary Antrum.

FRIDAY.—4.15 P.M., Dr. A. McDougall: A Point of Moment in the Treatment of Epilepsy.

Appointments.

DUNCAN, A. G. B., M.D.Aberd., D.P.H., has been appointed Medical Officer of Health, Kidsgrove Urban District.

ELLIOTT, G. M., M.B., Ch.B. Edin., Medical Officer of Health for the County of Selkirk and the burghs of Galashiels and School Medical Officer.

WHYTE, A. H., M.B., B.S. Durh., F.R.C.S. Eng. & Edin., Hon. Assistant Surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne.

WILSON, E. A., M.D. Edin., Junior Assistant Medical Officer, Cheshire County Mental Hospital.

National Hospital for Diseases of the Heart: TROTTER, W., M.D., M.S. Lond., F.R.C.S. Eng., Consulting Surgeon; CLEMINSON, F. J., M.Ch. Camb., F.R.C.S. Eng., Consulting Surgeon for Diseases of the Ear, Nose, and Throat.

Vacancies.

For further information refer to the advertisement columns.

Barry Urban District Council.—H.S. at rate of £200.

Birmingham, City Mental Hospital.—Asst. M.O. £350.

Cambridge, Addenbrooke's Hospital.—Cas. O. and Res. Anæsthetist. At rate of £130.

Cambridgeshire Tuberculosis Colony, Papworth.—H.P. At rate of £100.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Out-patient Registrar.

Colwyn Bay and Colwyn Urban District Council.—M.O.H., &c £800.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.P. At rate of £125.

Farringdon General Dispensary, Holborn-circus, E.C.—Surg. for Throat, Nose, and Ear Dept.

Greenwich, Dreadnought Hospital.—S. in charge of Out-patients.

Guy's Hospital, S.E.—Salomon's Infant Welfare Centre. M.O. 1½ guineas per session.

Holland County and Boston Borough Education Committee.—Dent. S. £450.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. At rate of £50.

Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.—H.P. and H.S. At rate of £100 and £75 respectively.

Hull City Education Committee.—Asst. Sch. M.O. £600.

Ipswich Mental Hospital.—Asst. M.O. £300.

Liverpool, Brownlow Hill Infirmary.—M.O. £500. Also Asst. M.O. £200.

London Hospital, E.—First Asst. and Registrar. At rate of £200.

Manchester Royal Infirmary.—H.S. At rate of £50.

Metropolitan Hospital, Kingsland-road, E.—Sen. and Jun. H.P. Sen and Jun. H.S. Also Two Cas. O.'s. Each at rate of £100.

Middlesex County Council Committee for the Care of the Mentally Defective.—Asst. M.O. £600.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Pathologist, £500, Asst. in Out-patient Dept. £150, and H.S. £125.

National Hospital for the Paralysed and Epileptic, Queen-square. W.C.—Res. M.O. £200.

Newark Hospital and Dispensary.—Res. H.S.

Plymouth County Borough.—Asst. M.O.H. £750.

Plymouth, Didworthy Sanatorium, South Brent.—Res. M.O. £600.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.

Royal Chest Hospital, City-road, E.C.—Phys. to Out-patients. £50.

Royal Northern Hospital, Holloway, N.—P.

St. Bartholomew's Hospital.—Asst. Ophth. S.

Seychelles Government.—Asst. M.O. and Res. S. Rs.6500.

Southend-on-Sea County Borough.—Asst. M.O. £600.

Wolverhampton and Staffordshire Hospital.—H.S. At rate of £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at Yeovil (Somerset) and Whitchurch (Salop).

The Home Secretary gives notice that, in consequence of the resignation of Dr. E. le C. Lancaster, one of the Medical Referees under the Workmen's Compensation Act, 1906, for the District of the Neath and Port Talbot County Court (Circuit No. 31), the appointment held by him is vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Oct. 28th.

Births, Marriages, and Deaths.

BIRTHS.

BOLTON.—On Sept. 30th, at Bedford Lodge, Belsize-grove, the wife of Dr. A. O. Bolton, of Leighton Buzzard, of a son.

GRAHAM.—On Sept. 20th, at Trimulgherry, India, to Major and Mrs. W. T. Graham, R.A.M.C.—a son.

ORAM.—On Oct. 4th, at Lee-terrace, Blackheath, the wife of E. H. B. Oram, F.R.C.S., of a son.

ORMEROD.—On Oct. 1st, 1925, to Mary (*née* Burton), the wife of Frank Cunliffe Ormerod, of 13, Welbeck-street, W. 1, and 39, Queensborough-terrace, W. 2.—a son.

MARRIAGES.

Colville—Ball.—On Sept. 30th, at Havant, Hants, Oliver Colville, M.D., of Bedlington, Northumberland, and Bath, to Kathleen, only daughter of Mr. and Mrs. Ernest Ball, of St. Margaret's, Drayton, Cosham, Hants.

Cuthbert—Taylor.—On Oct. 5th, at All Saints', Shooters' Hill, Captain Edmund Sheppard Cuthbert, R.A.M.C., to Annie Rose, elder daughter of Captain R. C. Taylor, R.H.A., (retd.), and Mrs. Taylor, of Plumstead.

Foote—Adair.—On Sept. 25th, at Holy Trinity Church, Sloane-street, S.W., Robert Rowden Foote, M.R.C.S., L.R.C.P. Lond., to Maureen, only daughter of Mr. and Mrs. G. E. R. Adair, Wellesley House, Lower Sloane-street.

Hammond-Williams—Barton.—On Oct. 3rd, at the Parish Church of St. Mary, Acton, Douglas Shepherd Hammond-Williams, L.D.S. R.C.S. Eng., to Violet Nellie, youngest daughter of Mr. and Mrs. Edward A. Barton, of The Cottage, Woodhurst-road, Acton, and Laleham-on-Thames.

Hilton—Hill.—On Sept. 16th, Reginald Hilton, M.B., B.Ch., M.R.C.P., to Gwenda Hill, M.B., B.S.

Hudson—Allard.—On Oct. 2nd, at All Saints' Church, Whitstable, Frank Hudson, F.R.C.S., to Christabel, eldest daughter of C. B. Allard, Tankerton, Kent, grand-daughter of the late W. Allard, F.R.C.S., Tewkesbury.

Mines—Gordon.—On Sept. 28th, at Sidbury Parish Church, Albert Gordon Austin Mines, R.A.M.C., to Marion Alice Gordon, youngest daughter of the late Alexander Hamilton Miller Haven Gordon, of Delamont, Killyleigh, Co. Down, Ireland, and Mrs. Gordon, of Ladymead, Sidford, Devon.

Prowse—Crellin.—On Sept. 29th, at St. Mary's, Leigh Woods, David Crawford Prowse, M.B., M.R.C.S., to Dorothy Emily Crellin, M.B., M.R.C.S., younger daughter of the late John C. Crellin and Mrs. Crellin, of West Mall, Clifton (late of Hoylake, Cheshire).

Rogers—Glasbrook.—On Oct. 2nd, at All Souls', Langham-place, London, Herbert Rogers, M.B., Ch.B., to Margaret Iris, eldest daughter of Mr. and Mrs. David N. Glasbrook, of Bryn-y-Mor, Swansea.

DEATHS.

Hunt.—On Sept. 30th in London, Edmund Langley Hunt, C.M.G., L.R.C.S. & P.I., Superintending Medical Officer Jamaica. Funeral took place at Golders Green Crematorium on Oct. 3rd.

Manby.—On Sept. 29th, at East Rudham, Norfolk, Sir Alan Reeve Manby, K.C.V.O., F.R.C.S., M.D., aged 77.

Stares.—On Sept. 28th, at The Limes, Swanley, Kent, Charles Lindsay Baker Stares, J.P., M.R.C.S. Eng., L.R.C.P. Lond.

Vernon.—On Feb. 12th, 1925, suddenly, at Montego Bay, Jamaica, Alexander Apfell Vernon, M.D. New York, M.R.C.S. Eng., L.R.C.P. Lond., aged 50 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE LONDON MEDICAL EXHIBITION: A REPETITION IN LIVERPOOL.

Both in scope and variety the London Medical Exhibition which was opened at the Central Hall, Westminster, on Oct. 5th and which closes to-day (Friday, Oct. 9th), is perhaps the most important of the many that have been organised since 1905. The attendance has been large; it has included appreciative visitors from London, the home counties, and the Midlands, and a fair number of medical men from overseas at present visiting this country. The success of these exhibitions is shown by the demand for a similar display more conveniently situated for medical men in the North of England, and to meet this demand a medical exhibition, similar to the London one, will be opened at the Philharmonic Hall, Liverpool, on Tuesday, Nov. 24th, for four days, closing on Nov. 27th. The London office of this new enterprise is the British and Colonial Druggist, Ltd., 194–200, Bishopsgate, E.C. At the London exhibition practically every branch of medical treatment receives recognition in some form, and both drugs and surgical instruments in their latest adaptation to progressive medicine and surgery find a place. Particularly noticeable is the large number of iodine and liquid paraffin preparations; the popularity of electro-therapeutic treatment is indicated by a variety of apparatus, and in this category may be included light treatment by means of quartz and other lamps. Another prominent feature of the exhibition is the obvious effort of the manufacturers of drugs to present them in a form pleasing to the eye as well as to the taste. The organisers are certainly to be congratulated upon the success of the exhibition no less than upon the production of the "London Medical Brochure," which is given away to visitors. This is a list of special medicines with their composition, therapeutic uses, and the name of the maker or supplier, and forms a ready guide for medical men who wish to try some of the newer remedies for particular diseases. A detailed account of the exhibition will appear in our columns next week.

INTERNATIONAL HEALTH ORGANISATIONS.

The prevention of disease as an international problem is now accepted as a commonplace, but international health organisations are of comparatively recent growth, and even the word international, now so familiar, only dates from 1780 when it was coined by Jeremy Bentham. International organisations trace their origin in the first place probably to trade, soon followed by intellectual and artistic exchange between nations, and they were also undoubtedly influenced by widespread religious interests as seen in the early Church Councils and in the Crusades. The earliest international congresses were of a scientific nature, the first of these being held in Germany in 1823, and it was not until 1864 that an association between nations for a common end took shape in the International Geodesic Association, which had as its object the accurate measurement of the earth. In 1851 the first international sanitary conference was held in Paris and prepared a draft convention which was never ratified, but from that time forwards the gradual development of the international aspect of public health took place until at the present day there are three important organisations concerned with this—the Office International d'Hygiène Publique, the Pan-American Sanitary Bureau of the American Republics, and the Health Organisation of the League of Nations, including both the Health Committee and certain divisions of the International Labour Office. A recent issue of Public Health Reports[1] from Washington contains an historical review of these organisations and traces their evolution up to their present-day established position.

After the First International Sanitary Conference of 1851, succeeding conferences were held in a spasmodic fashion until, in 1903, the Italian Government proposed a conference in Paris for the purpose of collecting into one agreement the existing conventions, and it was at this meeting that the Office International d'Hygiène Publique was created. An agreement between the powers was drawn up and signed at Rome in 1907, providing for the establishment of headquarters, funds, and staff, for the issuing of a monthly bulletin, and for a permanent committee which should meet once a year. The permanent committee met first in April, 1909, and but for the years of the war has continued to hold regular sessions each year. It has carried out important work; for example, with regard to plague, tuberculosis, Malta fever, water-supplies, and the standardisation of serums and other biological products, while the monthly bulletin, published without interruption since January, 1909, contains valuable epidemiological reports and tables, abstracts of articles on subjects pertaining to public health, and bibliographies on similar subjects.

---

[1] Washington, Public Health Reports, xl., No. 34, August 21st, 1925.

By the Covenant of the League of Nations the authority was given for an international health organisation under the direction of the League. The Office International d'Hygiène Publique found itself unable to participate in the activities of the League owing to certain important provisions in its organic by-laws, but to avoid the difficulties of a dual organisation an arrangement was made in 1923 whereby the International Office retains its regulations, powers, and its seat in Paris, and acts as the Consultative Council to the Health Organisation of the League, which consists in addition of a permanent health committee and a health section of the secretariat with its headquarters at Geneva. The League by means of this organisation has carried out a great amount of work, including, for example, the fighting of the typhus fever epidemic in Poland and Russia, an epidemic commission in Greece, and other preventive work in the Near East, while the standardisation of biological products and the interchange of public health officials by providing courses of "travel studies" are other important developments. The health section of the Secretariat of the League, under the direction of Dr. Ludwik Rajchman, is the executive organ of the Health Committee, and besides the work described above is responsible for issuing valuable epidemiological reports. The International Labour Office, an autonomous organisation within the League of Nations, has a division of industrial hygiene which has collected and published much information in regard to this subject, and has set up certain advisory committees, one of which on anthrax has made valuable contributions to the problem of combating this disease. Mention may here be made of the League of Red Cross Societies, an association of National Red Cross Societies founded in 1919, and now comprising 54 members, which maintains a permanent secretariat in Paris and does valuable work in close coöperation with the official international organisations by distributing propaganda on health matters throughout the world as well as carrying out courses in London for nurses from many different countries. It possesses a very fine collection of pamphlets, posters, booklets, and films on health matters, and forms an important link between the official bodies and the public.

The Pan-American Sanitary Bureau is the outgrowth of a series of international conferences of North and South American States which date back over a hundred years, and largely with a view to combating the ravages of such diseases as cholera and yellow fever at the sea ports the United States summoned an international conference to meet at Washington in 1881. This was followed in 1889 by a conference of American States at which every American Republic was represented, and where, among other questions, the subject of ship sanitation and quarantine was discussed. At the second conference of the American States in 1901–02 the International Sanitary Bureau of the American Republics was created, its name being changed in 1923 to the Pan-American Sanitary Bureau. Since its foundation this bureau, which is a permanent executive board with its headquarters at Washington, has been responsible for collecting and distributing information on public health matters, for giving expert assistance in the fighting of outbreaks of epidemic disorders, and generally carrying out the resolutions of the seven international conferences of the American States which it has organised since 1902.

COLONIAL HEALTH REPORTS.

Ashanti.

IN his report for 1923–24 Mr. John Maxwell, C.M.G., the Chief Commissioner, states that there were four deaths and five cases of invaliding of Europeans during the year under review, two of the deaths and two of the cases of invaliding being due to blackwater fever. The admissions to the European Hospital numbered 113, as compared with 194 during the previous year and 172 for 1921. The admissions to the Native Hospital numbered 1972, whilst 15,564 out-patients were treated during the year. These cases were of the usual kind, venereal disease, yaws, pulmonary affections, ulcer, and malaria being the most common. There was no epidemic throughout the year, and the health of the inhabitants was generally good. The sanitation of the towns (except Kumasi) and villages was satisfactory. With the opening up of the country by motor roads new villages adjacent to the roads have been built and the old villages distant from the roads have been deserted. This forward movement is particularly noticeable in the western province and is an extremely satisfactory condition of affairs. It indicates greater trust by the Ashanti in the protection of life and property which the administration affords, and also indicates that the Ashanti is fully alive to the greater possibilities of disposing of his products to travellers and others. These new villages, with the help of the political and sanitary officers, are all carefully laid out with fine broad streets, open spaces, and sanitary utilities. Kumasi, Obuasi, Bekwai, Juaso, Kintampo, and Sunyani are the principal towns, and the sanitation of these towns is under European and African officers. The population at the census of 1921 was 406,193, that of Kumasi, the chief town, at the end of the year being approximately 27,000. The town limits are a radius of one and a half miles from the fort and there are buildings scattered all over this area. The usual preventive measures were taken against insect-borne disease, including malaria, yellow fever, filariasis, infectious and epidemic diseases. There was, unfortunately, no improvement in the quality of the Kumasi water-supply, which is badly polluted by the presence of *B. coli.* There were no cases of cerebro-spinal meningitis, cholera, enteric fever, small-pox, or plague. The rainfall recorded at Kumasi during the year was 59·240 inches. Investigations have been made at Chebbi, near Nsuta, as to its suitability for a site for a sanatorium for the Gold Coast in accordance with the Secretary of State's suggestion. The situation is ideal and water-supply appears to be good and plentiful. It is 1200 feet above sea-level and is within two hours by motor from Kumasi, the road being good, except for the last three miles.

Grenada.

Mr. Herbert Ferguson, Colonial Secretary, in his annual report, states that the death-rate for 1923 (16·6 per 1000) is the lowest recorded in the annals of the colony. The number of deaths from dysentery decreased from 83 to 33, and from diarrhœa and enteritis from 329 to 283. Deaths from malaria were also fewer, being 74, as compared with 83 in the previous year. The population at the last census was 66,302. The Registrar-General points out "that the low death-rate coincided with a year of deficient rainfall, the latter having been 55·72 inches at Richmond Hill in St. George's, as compared with the average of 74·38 inches for the past 30 years. An examination of death-rate in relation to volume of rainfall over the past 20 years does not reveal any striking relativity between the two. As a rule a low rate of rainfall is supposed to accompany a decrease in the death-rate, but this is not invariably the case. A prolonged dry season followed by a short spell of heavy rains often leads to an outbreak of dysentery, diarrhœa, and enteritis, and thus, while the annual rainfall may be low, a corresponding reduction in the death-rate does not always follow. Last year there was no distinct spell of dry season, nor of heavy rainfall at any time, the latter being well distributed over each month. It is this equable distribution of rainfall throughout the year that has contributed to the low mortality."

Grenada, situated in the extreme south of the Caribbean Sea, is the nearest British island to the mainland of South America, with the exception of Trinidad and Tobago. The island is about 21 miles in length and about 12 miles in its greatest breadth. Its area is about 120 square miles, but including Carriacou, an island in the north, the area of the colony is 133 square miles. Grenada is mountainous and well watered by streams. St. George's Harbour, land-locked and deep-watered, is one of the most beautiful in the West Indies. There are two small lakes formed in extinct craters, one called the Grand Etang, being situated near the centre of the island 1740 feet above sea-level, while the other, Lake Antoine, is near the sea on the eastern coast. A sanatorium is established near the former. The climate can be classed as excellent, especially from December to May, when it is delightful. The range of temperature is small and tends to make the climate equable and healthy. The thermometer seldom reaches 90° F. in the shade or drops below 70°.

St. Helena.

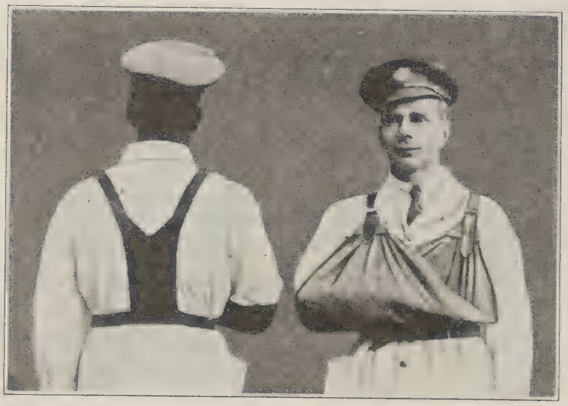
In his annual report on the affairs of this colony the Governor mentions that the civil population on Dec. 31st, 1924, was estimated at 3703, an increase of 43 over that of the previous year. The death-rate was 10·23 per 1000, compared with 7·66 in 1923. The number of births was 106 (not including four stillborn), as against 114 (and two stillborn) in the preceding year. The infant mortality was large, 11 out of the 38 deaths being under the age of 1 year. No specific reason can be assigned for this, the deaths being all from what might be termed natural causes in very young children. A mild epidemic of influenza was prevalent in the months of February and March, but there was no appreciable rise in the death-rate on that account. On the whole, the general health of the colony during the year was good; 169 persons were admitted to the hospital, being eight less than in the previous year. There were three deaths. The average number of indoor patients was ten. The mean temperature was 60·3° F., as compared with 62·0° in 1923. The total rainfall recorded at Hutts Gate for the year was 33·160 inches as against 45·740 in 1923.

THE NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.

THE annual dinner will be held at the Hotel Cecil, London, on Nov. 3rd, and Mr. Frederick Lawson, writing from the office of the *Daily Telegraph*, points out that the newsvendor works early and late that the public may be provided with their newspapers, while it is the purpose of the institution to provide on their behalf for pensions in old age or incapacity, or grants and other assistance to members, their widows, and orphans who may be in temporary difficulties. "Many newsvendors," he writes, "have only too little opportunity for providing for illness or old age, and the institution gives to those members of the public to whom the newsvendors render a daily service an opportunity to give their thanks in return." The funds of the Newsvendors' Institution, which was established in 1839, are carefully administered. There are at present 68 pensioners, whose welfare is constantly borne in mind. Sick parents are sent to convalescent homes, orphan children are cared for in selected institutions, and financial help is given in cases of need. Mr. Lawson is chairman for the year, and will be glad of offers from ladies and gentlemen willing to assist as stewards.

THE "EUPHOROS" SELF-ADJUSTING ARM-SLING.

IN appearance this sling is similar to the common form of support constructed from a folded handkerchief, but instead of being suspended from the back of the neck, the "Euphoros" is kept in position by straps passing over the shoulders and attached to a waistband, as is clearly shown in the accompanying illustrations, and the patient is thus relieved of any sense of carrying weight. One of the illustrations also shows that the back piece is curved so as to avoid the shoulder-blades, and this part of the sling, together with the belt, may be worn either under or over the coat. The sling is attached by buckles to the bands passing over the shoulders, thus making adjustment quite easy to the wearer; and a gusset at the elbow obviates the necessity for safety-pins and gives greater freedom to the arm. The "Euphoros," adaptable to the right or left arm, is made of a strong, light and durable black material, and is extremely comfortable to wear. Its merits certainly commend it, and it might well find a place in the emergency cupboard of every household. Messrs. Squire and Son, Ltd., 413, Oxford-street, London, are the agents for its sale.



The "Euphoros."

A FAMOUS SANITARY COMPANY.

THIS bright little book[1] tells how the City of London Sanitary Company was formed in 1908, of its regular service thereafter in autumn manœuvres, and of its personnel when the war broke out. On August 4th, 1914, there were two officers and 59 N.C.O.'s and men, and the numbers steadily grew to 80 officers and 1500 men overseas. Only men with sanitary knowledge or good education were taken, many of them obtained by advertisement in sanitary journals; there were sanitary inspectors, surveyors, builders' foremen, linguists, graduates in science, and others. Headquarters were at Chelsea, and scientific institutions in the neighbourhood freely helped. The men were taught about bacteriology, the causes of disease, the disposal of night soil, disinfection, the care of water and meat, and when trained they were fit to be N.C.O.'s. They were also taught to cook. In one respect they had good fortune, for their Q.M.S. was a professional caterer, and fed them well for a shilling a day, so that the mess fund, started by a gratuity of £50, got them equipment for instruction and recreation, a company magazine, rail tickets to go out of London for route marches, and ultimately, when the company was broken up, £500 to endow a memorial bed at the Westminster Hospital. After November, 1914, every British division had a sanitary section with it. The first duties overseas were supervision of the units, themselves responsible for the sanitation of their areas, but needing advice. The duty of the sections was to point out deficiencies, their privilege to help in putting them right, and tact generally got this done smoothly. Water analysis and chlorination, disinfection, baths and washhouses were special activities of the sections, nuisances and flies their great preoccupations. In 1917 men of no education were drafted into the company, but many of them proved to be useless or worse. There is a story of an infantry private who drank unapproved water, having first made German prisoners drink it, "and ye see they're all right." The book should be read by officers of sanitary companies and by all who expect to join them on mobilisation.

SUGAR AND ATHLETICS: A SHAKSPEARIAN ALLUSION.

To the Editor of THE LANCET.

SIR,—The Harvard Marathonians, in your leading article of Sept. 19th, found that eating candies was very reviving when exhaustion began to appear. They might have remembered Prince Hal's remark to Falstaff (*King Henry IV.*, Part I., Act iii., Scene 3): "If there were anything in thy pocket but tavern-reckonings, memorandums of bawdy-houses, and one poor penny-worth of sugar-candy *to make thee long-winded.*"—I am, Sir, yours faithfully,

M.A., B.Sc. St. And.

NURSERY PSYCHOLOGY.

THE National League for Health, Maternity and Child Welfare (117, Piccadilly) has issued a pamphlet entitled, "Every-day Psychology in the Nursery," being a selection from courses of lectures recently delivered by physicians and others under the auspices of the National Society of Day Nurseries. The six lectures reprinted in this book deal with various psychological subjects, including the use and abuse of suggestion with children, sex education, the part played by diet in the psychology of the child, and the children's evening hour. Each of these essays is good and practical, and should prove stimulating to all engaged in the training and care of children.

A NATIONAL INDICTMENT.[1]

"THE future is for the nations who are chaste." This saying of Tom Mann's is the concluding sentence in the book before us, an authorised translation of Mr. Paul Bureau's "Indiscipline des Moeurs," and it adequately sums up the author's beliefs. In an essentially scientific manner Mr. Bureau analyses the first of the three causes of what he terms the "great sickness" of France—namely, sexual licence, the others being alcoholic intemperance and lack of an efficient central governing and representative authority. He deals with much of the disagreeable side of life as it exists in that country, and it is particularly the attitude of the average man to sexual matters that he first attacks. For example, the attitude of what we should term a decent class family to the "amorous amusements of the young man" is that his enjoyment is innocent and free from moral blame "so long as the four accidents which may follow imprudent conduct are avoided: venereal disease, prosecution in the high court, an action for damages before civil courts on the charge of seduction or paternity." With the conduct of married people Mr. Bureau is no less severe in his condemnation, and although surprisingly influenced by much of the teaching of Malthus he is nevertheless wholeheartedly out against "neo-Malthusianism." The book, which Dr. Mary Scharlieb in an introduction describes as "at once terrible and fascinating," should certainly be studied by those interested in social and economic problems. The author's patriotism and his enthusiasm are unquestionable, and he tells his country frankly that if she "does not reform her habits not only will her glorious victory bring her no benefit, but, on the contrary, the war will have accelerated yet more swiftly the hour of her fall and will bring her nearer the hour of her final ruin." Hard words, but those who know France at all intimately realise that such words contain more than much truth, and the author's masterly analysis of the problem of sexual morality is not without interest to this country as well. We live in a glass house, as readers of the police news and the records of *causes célèbres* show.

Introductory Address

ON

RESEARCH IN THE MEDICAL SERVICES.

Delivered to the War Section of the Royal Society of Medicine on Oct. 12th, 1925,

BY LIEUT.-GENERAL SIR WILLIAM B. LEISHMAN,
K.C.B., K.C.M.G., F.R.C.P., F.R.S.,
DIRECTOR-GENERAL, A.M.S.; PRESIDENT OF THE SECTION.

AT the outset it is my purpose, if I can, to remove from your minds the impression that research is of necessity an esoteric matter, confined to mysterious laboratories, and that it can be carried out only by professors and specialists who have given years of work to their subject, who are a "peculiar folk," and talk in a tongue "not understanded of the people." It is true that much experimental inquiry demands expert knowledge, special equipment, and comes within the opportunity of comparatively few of us, but I prefer to give to the word research a much wider significance and to take it to cover any means by which we, of set purpose and on a deliberate plan, strive to add to the existing knowledge of the cause, the prevention, and the treatment of disease. I have on more than one occasion spoken on this subject and have urged in connexion with it a far closer collaboration for this purpose between clinician and specialist than exists at present.

THE PRESENT POSITION.

Let us examine in some detail our position as medical officers of the fighting services *vis-à-vis* this question of research. It is not my intention to dwell on the admirable research work which is in continual progress in our respective colleges and laboratories, nor to point out the moral of the incalculable benefits which the Services have enjoyed as a result of much of that work. This would leave no time to deal with anything else, and I prefer to speak of the present, and still more of the future, rather than of the past.

I am bound to admit that the present moment does not appear to be an ideal one for suggesting that, with our diminished personnels, over-worked officers should voluntarily add to their heavy work; but, after all, we are only passing through a period of depression, and such periods, familiar enough to those of us with long service, pass and have usually been followed by conditions better than those that preceded the negative phase.

Be that as it may, I know I am not exceptional in holding as a firm belief that there is a profound difference between work which, however conscientious and good, is more or less of a routine, and that which is varied and which brings with it continual new interests. Anything in the nature of research, understood in the broad sense I mentioned just now, belongs definitely to the latter category, and has the further great attraction that it brings us into that closer intellectual sympathy with our colleagues which is one of the results of the pursuit of a common purpose.

Advantages of the Services.

Let us now look for a moment at the very exceptional facilities and opportunities which we of the Services possess; they are indubitable and, I believe, far greater than those enjoyed by the great majority of our confrères in civil life. First, and most important, our material. Whether sailors, soldiers, or airmen, those of whom we have the honour to be in medical charge become, if we wish, our friends and comrades throughout their service; where they go we go, and their health and physical well-being is not only our charge but is to us an open book throughout their service, wherein we may read, and perhaps even write, as we will. From their examination as recruits till they leave the colours their physical standards and their medical history are recorded and they are under our daily supervision. What would not our civil brethren often give for such an intimate knowledge of the past history of a patient! There is nothing like it, except perhaps in some schools and institutions and in relation to some of the notifiable diseases such as tuberculosis. The fact that the men, like ourselves, are subject to discipline brings in another element of great value, inasmuch as it renders possible such things as systematic or periodical examinations and the employment of uniform standards of procedure, which are, as a rule, totally impracticable elsewhere.

As to the opportunities for medical research in connexion with this exceptional material, there is no need for me to remind my brother officers of both the abundance and the variety of the morbid conditions which come under our observation in officers and men and among their wives and families. This is less appreciated, unfortunately, by many outside the Services where there are still many misconceptions as to both the volume and the nature of our work, and it is not rare for us to read, or to hear, that our opportunities are meagre, that we see but the commoner ailments to which healthy young manhood is liable, and that the bulk of our experience is in the treatment of minor complaints and venereal diseases. This was not true even when I joined the Army in 1887, and nowadays, in that Service, the volume and importance of the medical and surgical work compares favourably with that of all but the largest of the metropolitan or provincial hospitals. The change of policy which has resulted in the concentration of the troops in a smaller number of large stations has been followed naturally by a similar concentration of the medical organisation—greatly to the benefit of the Army, the taxpayer, and ourselves. I am, naturally, not so intimate with the situation in the Navy, the Air Force, and the Indian Medical Service; but I have good reason to know that they are in most matters as favourably situated as ourselves, while the records of past meetings of this Section bear abundant evidence to the good use they make of their opportunities.

Medical and surgical material, then, is abundant and varied, both at home and abroad, and we are most favourably placed to observe our cases from start to finish and, if we wish, to follow them up afterwards.

The Value of Organisation.

Turning to another side, we can readily make use of our respective organisations for the employment of the technical aids to diagnosis and treatment with which medical science has been so greatly enriched in the last 30 years; and one acknowledges gratefully that we are able to maintain our equipment for theatre and laboratory in a condition well abreast of all modern requirements. Whatever tests may be considered as helpful to diagnosis or as accessory to treatment are readily available and, if the specialist and his tools cannot be brought to the patient, the patient, if necessary, is transferred to the hospital where he will find the pathologist, the radiologist, or other expert whose skill is needed. Further, should we feel that our own resources in skill or experience are insufficient in a difficult case we are indeed fortunate at home in being able to call upon one of our distinguished consultants, whose ready and valuable help it is impossible to acknowledge adequately. We are thus able, in all but the most isolated stations at home or abroad, to investigate fully all our cases, to observe their progress accurately, and to make permanent records in relation to any facts of importance. These are great assets for any medical man, and, if we do not benefit by them to the full, the fault is our own.

Such, then, being the present position as regards material and facilities in the Army Medical Service, and also, I am confident, in the sister Services, let us turn to the use which we are making, or may make, of them to further medical science by observation and research.

THE OUTLOOK FOR THE FUTURE.

As to the past, each Service has a record of research of which it has every reason to be proud, and even our youngest sister has lost no time in making her permanent marks on medical progress. As I have said, I do not intend to enumerate even the more important and outstanding of these researches, but will only point out that, for the most part, they were the work of men who had had the advantage of special training in some line and who enjoyed special facilities, either in the way of exceptional access to fruitful material or in the use of well-equipped laboratories. At the same time, this was far from being the case in all instances, especially in the past when specialism and laboratories were rare, and many most valuable contributions to knowledge were made by men who had to rely solely on themselves and had to create and utilise their own opportunities.

What would not many of our forbears have given to profit by the benefits which we have inherited? Apart from the volume of new knowledge which lies to our hand, we all enjoy the further inestimable privilege of going through an admirable post-graduate course, just at the moment in our professional life when we can benefit by it best; that is, when we are old enough to have acquired a wide experience of men and of other lands and are still young enough to retain energy and ambition. Whether or no our professional predilections are sufficiently defined to lead us to seek for further special instruction in a particular branch, we are all of us, at the least, given the chance of bringing ourselves well up to date in our rapidly moving profession.

The Opportunities.

The point which I now wish to make is this. In my view, everyone who has reached this stage in his Service career is well equipped to make valuable original observations on many lines of professional work, either alone or with the readily available help of his specialist comrades. Not that I would for a moment suggest that such work need be deferred till then, but one recalls how, in one's earlier years, one feared to slip up by publishing observations or views which, through our inexperience, might either prove not to be novel or to have been inadequately controlled and documented.

Apart from the desirability of attempting such research work for its own sake and for the general advancement of our profession, there is, I imagine, little need for me to emphasise its value to the individual. Not only would it make his professional life infinitely more interesting, but there is always the chance that a particular investigation might end in bringing to light something of great importance, one result of which would be, if justice is done, as it usually is in the end, that the investigator's name would become associated with the observation and he would find he had taken a definite step forward out of the class of "also ran." I would, however, warn anyone who, on the strength of this advice, felt inclined to try his wings in this direction that two qualities are essential to any chance of success—absolute honesty and infinite patience. One needs really something of the qualifications of the fly-fisher, for whom there is such hope in every cast that it will carry him happily through a blank day, leaving him with cheerful anticipations of the morrow.

One other word of counsel. Much careful and good observational work fails to obtain full acceptance and credit for lack of record of some observations or tests which a critic might consider essential to the acceptance of the conclusions. In such cases collaboration with a specialist colleague is most desirable, and is most valuable to each.

INDIVIDUAL RESEARCH: PLANNING THE WORK.

Let us now consider for a few moments what kind of inquiries might be set about and in what manner the material which lies to our hand might be utilised. You will, perhaps, forgive me the presumption of attempting to advise beginners in this matter on the slender ground of having been, in my past life, a specialist in one branch. Putting myself, as far as I can, in the position of a young officer who has not as yet attempted anything of this kind, I should begin by asking myself "In what line of professional work am I most interested and would most wish to become expert?" The answer, I am sure, would be clear and prompt. I should then sit down to think over the many branches of that subject, finally selecting one or two of them for a closer scrutiny. I should lay special stress on the cases which, in my own experience, had puzzled me and in which, for example, I had felt unsatisfied as to the current explanations of their ætiology or in which the treatment in common use had proved, in my hands, unsatisfactory. It would not be long, I fancy, before a certain number of such instances occurred to one. Of these I should select one or two and proceed to soak myself in the recent literature of the subject, incidentally subscribing to some of the technical journals dealing with it. One would soon realise that many others had encountered the same difficulties and would find oneself stimulated by their new points of view and their own conclusions. By degrees you would, I am sure, find yourself becoming more and more critical of these conclusions, so often expressed with dogmatic confidence, and you would begin to ask yourself "Why does this fail to convince me?" or "How am I to reconcile this result with what has been recorded by X, Y, or Z?" Next in order comes the stage at which one begins to think "Would it not be possible to settle the point if I were to do—what?" If one accepts the mental challenge *that* is the starting-point of a specific piece of investigation, and one must then begin to plan the campaign. Assuring oneself, in the first place, that sufficient material is already available, or can be made available by a little private organisation, you ask "How can I make and record these observations in such a way that a clear-cut answer may be obtained to the questions I have asked myself?" In this it must be kept clearly in mind that you have to convince not yourself only but others who, when they come to read your work, will be quick to notice the absence of certain relevant details or the inadequacy of your "controls." It is impossible to take too much trouble over this planning of the inquiry, for, if every fallacy is not thought of beforehand, and guarded against as far as possible, one may waste much effort and have to start afresh.

Unexpected difficulties, failures, interruptions, are the daily bread of the inquirer, but, if met with cheerful philosophy, and still more if one is wise enough to have prepared more than one string for one's experimental bow, one may confidently anticipate reaching a result worth communicating to a society or journal and will have achieved an altogether new outlook on professional work and acquired that admirable thing a new interest in life.

The Fallow Fields.

Each man has different tastes and different aptitudes, but, in the extremely varied work which falls to us in the Medical Services it would indeed be strange if one could not find, within working distance, both the subject and the material for commencing such an inquiry as I have outlined. The tropical diseases are bristling with unsolved problems of ætiology, of treatment, and of prevention, and our opportunities in this line when on foreign service are unbounded. The Navy and the Air Force have, I take it, no lack of unsolved problems special to themselves, while in the Army there are a host of morbid conditions, some of them of first-grade military importance, in which our special facilities should give us a better chance of adding fresh knowledge or of clearing up difficulties than falls to the lot of most of our brethren. Again, to the considerable number of us to whom preventive medicine makes a stronger appeal than clinical work, the difficulty will be to choose one out of the hosts of problems which are presented to us by the rapid development of this subject.

COLLECTIVE RESEARCH.

So far I have been speaking of the individual inquirer who wishes to choose and follow up for himself a particular subject. Let me now say a word or two on collective research, a method of inquiry which so far has not been very widely used in the Services. By this is meant that a selected problem is investigated by a number of workers in different places who follow an agreed plan and conform to certain rigid standards as to the material and the methods to be employed. I have always thought that there were great possibilities in connexion with this method and that the conditions which should make for success were exceptionally favourable in the Medical Services. In the case of the Army our research organisation is readily adaptable to such a method, and a certain number of such investigations have been commenced since the Directorates of Pathology and Hygiene were created. As no doubt you are aware, in each of these subjects our Director has the advantage of a technical Advisory Board to which highly qualified civilian experts have been nominated. At their meetings subjects possibly suitable for such research are examined and, if one is chosen, the details of the inquiry, the methods to be employed, the mode of recording, collecting, and analysing the results, &c., are fully discussed and decided upon. The detailed plan is then communicated to the specialists in suitable commands, who get down to work on a common plan and using a common technique. I may enumerate a few of the pathological subjects so chosen, merely by way of illustration. (1) Influenza: the incidence of Pfeiffer's bacillus in the sick and in contacts, in the presence and in the absence of epidemics. The use of vaccines. (2) Latent sepsis: the value of vaccines prior to operation. (3) Catarrh: inquiry into bacteriology and prophylactic use of vaccines. (4) Typing of strains of diphtheria, cholera, and dysentery bacilli encountered in different countries. (5) The Schick reaction. (6) Parallel testing of the Sigma and Wassermann reactions. (7) Sand-fly fever.

These and other subjects have been explored in this collective way with, in some instances, substantial and encouraging results. I need hardly add, especially in the present difficult times, that we cannot command success; a particular epidemic may dwindle and disappear, or the other material may not be forthcoming in sufficient quantity. More frequently, however, it is one of these inevitable but irritating "exigencies of the Service" which has called a premature halt to a promising line of inquiry. I trust, however, that such efforts may not be abandoned since these collective inquiries are of value not only because they multiply results and tend to accelerate progress, but because the work and results of one observer form a useful check on those of another. Again, the mere fact that workers at a distance from one another are engaged on the same problem, and confronting the same difficulties, stimulates inter-communication and tends to break down that feeling of isolation which may sometimes become so irksome when one is working alone.

Its Value to Civil Medicine.

Before leaving this subject I would add that the method is capable of being of service to our civil brethren. There are many inquiries of medical, physiological, or sanitary importance which, because we are very busy people and because the problems are not perhaps of very direct military importance, we have not undertaken in the Services. At the same time, thanks to the favourable conditions of which I spoke at the beginning of my address, the Army, Navy, or Air Forces offer a field for their investigation under almost ideal conditions of observation and control. We have received, and continue to receive, so much ungrudging help and advice from our civil colleagues that we should, indeed, be ungrateful if we did not in return do everything that we could to assist them, whenever this is within our power. I am glad to know that something has already been done for them in this way, and I hope that we may be able to do more.

As regards research and observation of the more strictly clinical character I may add that, in the case of the Army, we have now the great advantage of the advice and controlling direction of our own consulting surgeon and consulting physician, and I am confident that their assistance and counsel would, if required, always be most readily available.

To conclude, I have been urging upon you that we should endeavour to secure a larger output of medical research from the Services, and have suggested that this is well within the power of many who have not so far embarked on it. I have done so for the following reasons: First, because it is our bounden duty to leave nothing undone which we can do to maintain or improve the health of the fighting forces, and to anticipate and prevent medical catastrophes in the future, not only by utilising new knowledge, but by adding to it. Second, because I know nothing better calculated to maintain a man's professional interests as well as to keep him out of the groove which may become so dangerously deep as our Service advances. Finally, it is only by contributing our full share to medical progress that we can hope to maintain the high prestige gained for our respective Services by those who have gone before us.

THE TOXIC EFFECTS OF LEAD ADMINISTERED INTRAVENOUSLY.*

BY W. BLAIR BELL, B.S., M.D. LOND.,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF LIVERPOOL; OBSTETRICAL AND GYNÆCOLOGICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL; HON. FELLOW, AMERICAN GYNÆCOLOGICAL SOCIETY; HON. FELLOW, AMERICAN COLLEGE OF SURGEONS; HON. DIRECTOR, CANCER RESEARCH COMMITTEE, LIVERPOOL; HON. PRESIDENT, GLASGOW GYNÆCOLOGICAL SOCIETY;

W. R. WILLIAMS, M.D. LIVERP., F.R.C.S. ENG. AND EDIN.,
HON. ASST. SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL; HON. DEMONSTRATOR ANATOMY, UNIVERSITY OF LIVERPOOL; ASST. SURGEON, CANCER RESEARCH COMMITTEE, LIVERPOOL;

AND

L. CUNNINGHAM, M.B. CAMB., M.R.C.P. LOND.,
HON. ASST. PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL; ASST. PHYSICIAN, CANCER RESEARCH COMMITTEE, LIVERPOOL.

No one hitherto has had an opportunity of observing the toxic effects in the human subject of measured quantities of lead administered intravenously at known intervals. The accuracy of the observations about to be recounted makes them of some importance in any consideration of lead poisoning.

The injections, the effects of which we have been able to observe, have been given in the course of the treatment of malignant neoplasia, to which reference has already been made on previous occasions,[1] [2] and to which we shall again refer in the next and last paper of this series. In that paper, too, the more detailed procedures in connexion with the administration of lead will be recorded. Here it will be sufficient to give a general outline of the method. Some 200 patients in all have received injections.

METHOD OF PROCEDURE.

The actual form in which the lead has been administered has varied considerably from time to time, but the last 58 cases have been treated almost entirely by intravenous injections of metallic lead in colloidal form. In the early cases lead acetate, lead iodide in a partly colloidal state, and compounds of lead with thyroiodin and with hæmoglobin were used. Before treatment was commenced the blood of every case was carefully examined, and, as far as possible, full red and white cell and differential cell counts were made, and the blood-urea and sometimes blood-sugar were estimated. The urine was also exhaustively analysed, and in cases about which there was any doubt as to renal efficiency a urea-concentration test was performed. The hepatic efficiency was also examined, especially in cases in which there was involvement of the liver or jaundice due to extrinsic causes.

---

* This investigation was undertaken on behalf of the Liverpool Cancer Research Committee.

[1] Bell, W. Blair: THE LANCET, 1922, ii., 1005.

[2] Ibid., 1924, i., 267.

During treatment all these methods of investigation were carried out whenever possible at intervals, either after each dose or after every few doses; especially was the blood examined for stippled red blood corpuscles, and the urine for albumin.

SYSTEMS AND ORGANS INVOLVED IN THE TOXIC EFFECTS OF LEAD.

The toxic effects of lead were noted on the following systems and organs: (1) the blood and blood-forming organs; (2) the alimentary system; (3) the nervous system, including the retina; (4) the kidneys; (5) the liver.

FACTORS CONCERNED IN THE PRODUCTION OF TOXIC EFFECTS.

Susceptibility of the Individual.—In general, it has been found that there is a great difference in individual tolerance to lead. Some patients showed signs of poisoning after quite small amounts had been administered, whilst others showed no untoward symptoms, although relatively large quantities had been given.

Body-weight.—It has appeared that the quantity necessary to produce toxic symptoms has varied with the body-weight of the patient; for example, a patient weighing 14 st. can usually tolerate more lead than a patient whose body-weight amounts to 7 or 8 st.

Age of the Patient.—It has also been held that there is an age factor in regard to the rapidity and intensity of the toxic effects of lead. We have found that relatively larger amounts could be given to patients between 55 and 65 years of age. It was formerly thought that young people tolerated lead better than older persons, but we have observed that a slightly higher average dose was necessary to produce toxic symptoms in patients between the ages mentioned than in younger patients.

Sex of the Patient.—It appears that the male is more tolerant than the female to the toxic effects of lead, as the following figures tend to demonstrate:—

Maximum and Minimum Amount of Pb required to Produce Toxic Symptoms: Average for all Ages.

Maximum.		*Minimum.*	
Males.	Females.	Males.	Females.
0·34 g.	0·29 g.	0·1 g.	0·04 g.

It must, however, be remembered that the average weight of men is greater than that of women.

Size of Malignant Growth.—It has, too, constantly been observed that there is a definite relation between the sizes of the growth to be treated and the amount of the lead which can be tolerated. A patient with a large sarcoma in the abdomen, for instance, would show no signs of lead poisoning until very considerable quantities had been given; whereas a patient with a small carcinoma of the œsophagus might show symptoms of poisoning when a relatively small amount had been administered. This relation between the size of the tumour and the amount of lead which is tolerated is impossible to demonstrate in figures, but it is a clinical fact which we have repeatedly observed. The importance of this will be discussed in another paper.

From what has been said in the preceding paragraphs it will be noticed that there are many factors concerned in the facility or difficulty with which lead poisoning may be produced in patients under treatment, and the various factors may interact so as to produce a complex arrangement that is impossible to estimate in any statistical manner, and it is this that makes treatment of malignant disease with lead extraordinarily difficult.

In our experience repeated small doses over a long period of time produce a dangerous cumulative effect. On the other hand, a few large doses administered at long intervals, considerably exceeding in total quantity of lead the amount given in small repeated doses, may, after the initial symptoms, leave no bad effect whatsoever.

EXCRETION OF LEAD.

As is well known, lead is but slowly excreted from the body. Our own observations indicate that malignant growths have the power of attracting lead, as a result of which we have found that the metal may become locked up in the tumour to an extent that is infinitely greater than occurs in the normal tissues of the body. We have also made observations on the relative excretory processes of the kidney and bowel. The urine and fæces were collected from two cases to which heavy initial doses of lead, amounting to 0·15 g. lead, had been administered in a single dose. In these cases it was found that the amount of lead excreted by the kidney was very large, and that only a small proportion appeared in the fæces.

TOXIC EFFECTS OF LEAD ON THE BLOOD AND BLOOD-FORMING ORGANS.

Red Cells.—The effects of lead on the red cells may be grouped as follows: (*a*) punctate basophilia; (*b*) polychromasia; (*c*) abnormal forms; (*d*) anisocytosis and poikilocytosis; and (*e*) anæmia.

Punctate Basophilia.—This is one of the earliest signs of lead poisoning. Some writers have stated that this phenomenon occurs in normal blood; we are, however, convinced that this is not so; it has only been found in a single case in our large series of blood examinations before lead has been administered. Undoubtedly, of course, it occurs in other pathological states, especially severe anæmias.

The appearance of the granules in the red cells, which give rise to the name "punctate basophilia," when seen in a blood film stained by Leishman's method, varies. In a well-marked example they are seen as bright blue stipples, numbering from 10 to 20 or even more, inside the red cells. The size of the blue stipple varies greatly; in some cases they are large, when the condition is known as "coarse basophilia"; in these instances the blue bodies are frequently arranged round the periphery of the cell. In other cases they resemble very fine dots scattered uniformly throughout the cell. In those cases in which there is polychromasia it is possible that the appearance is due to the granules having become broken up and diffused throughout the cell.

The actual number of stippled cells found in any film of blood is also subject to great variety. In a severe case of lead poisoning it is possible often to find an average of two stippled cells in each field under the 2 mm. objective; this, however, is rare. More commonly one stippled cell is found in every five or six fields. When the patient shows no other evidence of lead poisoning, it may be possible only to find one or two stippled cells after a prolonged search. The time of appearance of the stippled cells in the blood, after the intravenous administration of lead, depends on two factors: (*a*) the amount of lead given, and (*b*) the susceptibility of the patient from the many points of view already discussed. The smallest total amount of lead which produced stipples in our cases amounted to only 0·02 g. The earliest time at which stipples have been observed was three hours after a single injection amounting to 0·1 g. of lead. Generally, great variations have occurred both in the time of appearance of the stipples, and in the amount of lead necessary to produce them. No doubt susceptibility is a factor of importance in this matter.

The exact significance of stippling has never been determined with absolute precision. By some, it is considered to be a degenerative process, by others regenerative. Recent observers incline to the belief that the phenomenon is due to degeneration in the red cells owing to the fact that in the bone-marrow stippled cells are not found, and also because the phenomenon is associated with other pathological processes than lead poisoning. Moreover, it appears probable that the basophile stipples are of cytoplasmic origin, and are not, in fact, fragments of the nucleus of a normoblast. Indeed, we have frequently observed normoblasts containing a perfectly normal nucleus, in which coarse basophile stipples have been scattered in the cytoplasm around the periphery.

Polychromasia.—This is a very common phenomenon. It consists of a diffuse grey-blue coloration of the red cells stained by Leishman's method. Reference has been made to the suggestion that this is due to diffusion throughout the cell of the basophile stippling. It is possible, also, that it may be connected with changes in the constitution of the hæmoglobin in the red cells in the circumstances under consideration. We have observed this phenomenon frequently during the recovery of the patient from the effects of lead.

Abnormal Forms.—The presence of nucleated red corpuscles is not very uncommon. When present they are invariably associated with considerable anæmia and stippling of the red cells. Sometimes, as already mentioned, the nucleated red cells themselves contain stipples. From this it is obvious that degenerative processes associated with the formation of stipples, whatever they may be, can occur at a very early stage in the life of the red cell.

Anisocytosis and Poikilocytosis.—These phenomena have only been seen in association with more or less profound anæmia.

TABLE I.—*Summary of Patients Showing Changes in Red Blood Cells after the Administration of Pb.*

No. of patients (117 cases) : Males (M.), 31 ; females (F.), 86.
No. of patients showing—

1. Stippling of the red corpuscles (76 cases) ..	M.	24
	F.	52
2. Stippling of the red corpuscles + N.R.C. (24 cases)	M.	6
	F.	18
3. Polychromasia (14 cases)	M.	2
	F.	12
4. Stippling, nucleated reds, poikilocytosis (1 case)	F.	1
5. Stippling, nucleated reds, polychromasia (2 cases)	F.	2

Average amount of lead producing—	Stipples ..	0·14 g.
	Polychromasia ..	0·157 g.
	Nucleated reds ..	0·138 g.
Average time for production of—	Stipples ..	12 days.
	Polychromasia ..	13·4 days.

and in six of the most recent cases where nucleated red corpuscles appeared they were observed on the fifth day.

Anæmia.—Anæmia associated with chronic lead poisoning has long been observed, and, indeed, is a peculiar feature in the appearance of workpeople engaged in the lead trades. An eminent Recorder in the North Staffordshire area informed us that time and time again he was able to see in witnesses in his court evidence of the pallor produced by the absorption of lead. We have observed that although a considerable degree of anæmia, as shown by the hæmoglobin-content may be present, it is not invariable to find this associated with a decrease in the red cell count. We have, however, been able to observe all degrees of the condition, from the very mildest to that resembling the severest form of aplastic pernicious anæmia. Reductions of 750,000 red blood corpuscles after the administration intravenously of 0·2 g. of colloidal lead have been noted ; but blood cell counts as low as 3,400,000, and in one case even 1,400,000 have been seen.

As already indicated, far more striking than the diminution in the number of red blood corpuscles may be the reduction in the hæmoglobin-content. Table II., which consists of a few cases selected at random, will serve to illustrate these points.

It will be seen from Table II. that lead causes a relatively greater diminution in the hæmoglobin-content of the blood than in the number of red cells, although this is not invariable.

It follows that with such marked blood destruction all the symptoms of serious anæmia may be present—pallor of the skin and mucous membranes, headache, lassitude, and muscular weakness. In several of our patients a blood transfusion has been deemed necessary before treatment could be continued. In one case, however, in spite of repeated transfusions, very little benefit was obtained ; the lead seemed to have destroyed the blood-forming power of the bone-marrow.

TABLE II.—*Relation Between the Hb. Content and the R.b.c. and the Amount of Pb Administered.*

Case No.	Hb. percentage before treatment. (R.b.c. in millions.)	No. of inject.	Mass of Pb.	Hb. percentage after treatment. (R.b.c. in millions.)
			(g.)	
44	73 % ; r.b.c., 3,900.	5	0·18	50 % ; r.b.c., 3,660.
34	95 % ; r.b.c., 6,500.	11	0·48	65 % ; r.b.c., 3,950.
46	88 % ; r.b.c., 4,800.	5	0·35	82 % ; r.b.c., 4,625. 17 days later Hb. 70 % ; r.b.c. 4,050.
48	90 % ; r.b.c., 4,725.	4	0·24	82 % ; r.b.c., 3,950.
32	90 % ; r.b.c., 5,900.	11	0·53	52 % ; r.b.c., 3,050. 1 more inject., 10 c.cm. B.
			0·55	42 % ; r.b.c., 2,800. 1 more inject., 15 c.cm. B.
			0·58	36 % ; r.b.c., 2,340.
47	83 % ; r.b.c., 5,125.	13	0·43 0·05 } 0·48	55 % ; r.b.c., 4,950.
23	95 % ; r.b.c., 7,100.	37	0·83	50 % ; r.b.c., 4,400.
189	84 % ; r.b.c., 4,750.	2	0·2	59 % ; r.b.c., 4,000.
185	88 % ; r.b.c., 5,150.	3	0·3	75 % ; r.b.c., 3,850.

The rate of recovery from lead anæmia is, of course, a most interesting matter. In those cases, such as the one just described, who had submitted to frequently repeated small doses, recovery from the anæmia is rather a lengthy process. On the other hand, when patients have received several massive doses their recovery seems almost instantaneous.

The appearance of patients who have recovered from malignant disease under treatment, and are seen some months or years later, is that of the most vigorous health, without any abnormality of the blood cells. This point was emphasised by Dr. Adami recently at a review of our cases.

Another phenomenon to be observed with considerable frequency in blood films is the curious distribution of the pigment in the red cells. They assume the appearance of a lifebuoy with the red pigment around the periphery and an apparently clear zone in the centre ; this, of course, is a common phenomenon in anæmia, but as we have observed it so repeatedly we think it well to call attention to it.

BONE-MARROW.

We have examined the bone-marrow from animals which have died in the laboratory from lead poisoning. In no case have we seen stippled cells in this tissue ; indeed, like other observers, we are at a loss to say in what important particular this organ is affected. A lengthy investigation into the normal structure of this complex tissue has not enabled us to discover any important difference in the bone-marrow of healthy and lead-poisoned animals. That it is involved is undoubted, as the stage of inertia is reached in certain cases, to one of which we have referred, when the marrow seems to have given up the effort of throwing off normoblasts into the blood-stream.

CHANGES IN THE WHITE CELLS.

These may be grouped as follows : (*a*) leucocytosis, (*b*) relative lymphocytosis, (*c*) slight eosinophilia, (*d*) increase in other granular and streaky forms, and (*e*) leucopenia.

Leucocytosis.—Leucocytosis has, of course, been observed in association with malignant processes. Whether this is due to malignant growth is doubtful ; it seems likely that it may be the result of the infection that so often supervenes owing to autolytic processes in malignant neoplasms. Bearing this fact in mind, we have endeavoured carefully to observe whether the administration of lead alters the white cell count. When moderate-sized doses of lead have been given there has not been any very great increase in the number of white cells, 14,000 to 15,000 being the maximum number counted. In one instance, however, in which the patient received 0·2 g. lead in a single dose, leucocytosis was pronounced, the leucocyte count rising to 58,000 within 48 hours of the injection. It would appear that the earlier the counts are made after an injection, the greater likelihood there is of finding some degree of leucocytosis, for the number of white cells appears rapidly to diminish until the normal level is reached. (Table III.)

TABLE III.—*Showing Leucocytosis after Administration of Pb.*

Normal w.c. count: 6500.

Case.	No. of injects.	Mass of Pb.	Leucocyte count.	Time after commencing treatment.
		g.		
178	4	0·425	9,200	—
79	10	0·3	9,500	3 months.
174	1	0·2	52,500	2nd day.
91	4	0·16	14,500	—
105	20	0·57	12,000	—
138	2	0·019	15,000	—
146	3	0·0275	15,000	In 9 days.
	11	0·1825	42,000	—
149	6	0·086	12,000	1 month.
53	22	1·3	10,000	—
23	14	0·39	11,250	4 months.
168	4	0·11	15,000	—
23	3	0·025	13,750	6th day.
45	2	0·06	13,700	3rd day.

Relative Lymphocytosis.—Many observers have described relative lymphocytosis in association with lead poisoning. This, however, is by no means common, and very rarely does the percentage of lymphocytes exceed that of leucocytes. The counts in Table IV. are illustrative of a certain degree of lymphocytosis.

TABLE IV.

No. of w.b.c.	Poly-morph. (%).	Lymph. (%).	Large mono-nuclear cells (%).	Eosino-phile (%).	Mast. (%).
3,900	46′0	48·0	1·5	4·5	—
13,750	51·3	31·6	10·6	6·0	0·6
3,500	52·5	27·0	20·5	6·0	—

These, however, are somewhat unusual, and, taking an average of a large number of cases of differential counts, the percentage figures work out as follows: polymorphs, 63·6; lymphocytes, 20·7; large mononuclear cells, 7·4; eosinophiles, 3·7; mast cells, 1·5; and transitionals, 2·6.

It will be seen in lead poisoning that although a relative lymphocytosis may occur, yet it is not constant, and with almost all cases the relative numbers of leucocytes and lymphocytes are approximately normal. The slight increase in the eosinophile cells appears to be fairly common. In some instances this was very marked, and very many beautiful specimens were seen with large pink granules. On one occasion they equalled 8·3 per cent. of all the leucocytes present, and as high a ratio as 6 per cent. has been observed on several occasions. Yet, as is seen from the preceding table, taken on the general average of a large number of differential counts, the eosinophile cells represent only 3·7 per cent. of the total number of leucocytes—a slight but definite increase above the normal.

Increase in other Granular and Streaky Forms.—A number of curiously-streaked forms of white cells may be found. Many of the cells already described in the table were as large as polymorphs, and show a streaky cytoplasm. In size and shape they resemble the large hyaline cells. Occasionally there are found cells which closely resemble the ordinary polymorph, except that the granules, instead of staining pink with eosin, taken on a purple tinge.

Leucopenia.—Leucopenia is rarely seen. There seems a tendency rather that, if there be a change, it is towards leucocytosis. The particulars given in Table V. illustrate the possibility of this condition.

TABLE V.—*Showing Leucopenia.*

Case No.	W.c. count before treatment.	No. of injects.	Mass of Pb.	Leuco-penia.	Time.
			g.		
1	6,200	4	0·16	3,900	22 days.
14	8,120	24	0·2	6,250	7 months.
34	9,375	27	1·056	4,217	15 ,,
				5,000	17 ,,
150	10,625	16	0·674	3,500	11 ,,
		17	0·774	6,200	12 ,,

It will, however, be seen from the tables given that there is nothing specific or definite in regard to the change seen in the white cells as there is in the red cells.

THE ALIMENTARY SYSTEM.

The signs and symptoms discussed under this heading are the following: (1) Blue line on the gum edges; (2) nausea and vomiting; (3) intestinal colic; and (4) constipation and diarrhœa.

Blue Line on the Gum Edges.—In our experience this has been an uncommon occurrence; it has only been definitely observed in three cases. The explanation of the infrequency with which this phenomenon—so often considered a classical sign of lead poisoning—is observed is probably due to the method of administration. The blue line is, of course, due to the conversion of lead into lead-sulphide by the H_2S generated by decaying vegetable matter in the mouth. In these circumstances it is easily understood that if lead gained entrance to the system through the mouth, en route either to the lungs or the intestinal canal, the blue line on the gums would readily be produced; and these methods of admission are probably the common ones in industrial lead poisoning. In the three cases in which we have seen the blue line, lead had been administered over a relatively long period. When given in massive doses, as now, it is unlikely that it will be seen. It has always been stated that the blue line is persistent over a long period of time, but in our cases it disappeared in two or three weeks. This further illustrates the difference in the manner of production when the lead is administered intravenously from that of the more superficial staining observable in industrial lead poisoning.

Nausea and Vomiting.—It occasionally happens that a patient complains of intense nausea a few hours after the first or second injection of colloidal lead. It is difficult to believe that in these circumstances the symptom is due to lead alone; it is probable that the foreign proteins in the colloidal solution are responsible for the effect produced. The true nausea and vomiting due to lead generally occur later, after the administration of the metal; the nausea and vomiting may then be very bad, and may last for several days. Moreover, it is more persistent in some of the cases in which it has not been observed after the earlier doses; this indicates that the accumulation in the system of a certain amount of lead may be necessary in some patients before these symptoms are produced. Since we have given massive doses the cumulative effect has been well demonstrated. Before June, 1924, the solution used never contained more than 0·1 g. per cent. of lead; after that date we commenced to use a very strong solution containing 0·5 per cent. of lead. The average mass of lead required to produce vomiting with the weaker solution was 0·37 g., whereas with the stronger solution 0·22 g. was sufficient. This is in keeping with the production of other toxic symptoms; with the heavier doses they appear earlier, but, fortunately, disappear sooner; with the smaller doses we were inclined to continue blindly until very serious symptoms supervened—symptoms which could not well be relieved with any degree of certainty.

Lead sickness is a very distressing condition both for the patient and the doctor. As a rule, the patient can take no food whatsoever, and some of our patients have lived on water (if they did not reject that) and saline with glucose per rectum for several days. It is important, too, to bear in mind the fact that the patient may have gone home for some days before the vomiting occurs. In one case no symptoms supervened until three weeks after an injection, and the patient became seriously ill, and remained so for ten days. In such circumstances, of course, acidosis supervenes. We have known of no cases in which the patient has not eventually recovered, and, indeed, a few weeks later expressed themselves as feeling better than before. The susceptibility of the patient, to which we have already referred, plays a large part in the onset and severity of these symptoms.

Intestinal Colic.—Until the administration of the heavy doses of colloidal lead, we had never seen a case of lead colic. During the last year, however, it has been noted in a large proportion of all the cases treated; very often it is an accompaniment of the attacks of nausea and vomiting, which we have just discussed, and it usually comes on at the same time. The pains may be extremely severe and last several days; eventually, within a short time, they entirely disappear. It is extremely difficult to relieve the pain in severe attacks of intestinal colic; indeed, morphia and atropin are the only drugs we have found of service.

Constipation and Diarrhœa.—We have seen very few cases of constipation that could definitely be attributed to the effects of lead. So many patients are constipated in ordinary circumstances and rarely complain that the injections have made them more so. It is important, however, that patients under treatment should be closely questioned, and saline aperients should be given if constipation is present. We have not been able to connect this disorder with intestinal colic, just mentioned. Diarrhœa we have not seen, except in one or two cases after a very massive dose of lead, and then it appeared to be due to an anaphylactic shock produced by the proteins present in the solution rather than to the lead itself.

NERVOUS SYSTEM, INCLUDING THE RETINA.

The nervous phenomena produced by lead poisoning may be divided into two groups: (1) psychopathies, and (2) neuropathies.

In the early stages of our work we had three cases in which the patient became mentally deranged, no doubt due to what has been called lead cephalopathy—that is, to changes produced by lead in the brain.

In only one case were the symptoms serious. The patient was a male with an extensive carcinoma of the œsophagus; he became unmanageable, and apparently had delusions that he was being starved.

In another case, a man with extensive carcinoma of the floor of mouth, the patient became strange in his manner and taciturn; there was no violent outbreak, and the patient was sent home in a slightly improved condition so far as his mentality was concerned.

In the third, the patient, when at home in an interval between the administration of injections, committed suicide, but it was hardly fair to attribute this to the administration of lead, for he was a young man who was naturally in a state of considerable mental agitation, because he knew that he had cancer of the bladder.

With regard to neuropathies, such as wrist-drop, we have seen none, and this has been a source of considerable surprise, for we know that involvement of certain peripheral nerves has been regarded as almost inevitable in lead poisoning.

The Retina.

Four patients have complained of eye symptoms. In two instances they suffered from temporary loss of vision, the condition lasting only a few hours, complete recovery supervening.

In the other two cases, however, there was considerable œdema of the retina, and in one there was optic atrophy, the patient becoming almost completely blind. It was important to note that the œdema of the retina in each case was associated with generalised œdema of the body and a considerable degree of albuminuria. It is probable that the lesions in the kidney were responsible for the retinal changes.

These symptoms only occurred in the earliest stages of our work, but we feel that they should be emphasised as a serious warning of the dangers associated with this treatment.

THE KIDNEY.

Sometimes the earliest and often the most obvious toxic action of lead is on the kidney. The extent and duration of the damage seem to depend both on the amount of the dose given at one particular time and also on the total quantity of lead administered, even when given in small doses.

TABLE VI.

* Non-protein nitrogen.

We have attempted to study the effect of lead therapy on renal function from five main points of view: (1) clinical manifestations; (2) changes in the blood-urea; (3) changes in the urea-concentrating power of the kidney; (4) changes in the urine; and (5) pathological changes in the kidney.

Clinical Manifestations.—Usually, after small doses of lead, clinical manifestations are not apparent. Occasionally, however, diminution in the secretion of urine and œdema may occur together with changes in the urine. The appearance of symptoms, or of other evidence of renal impairment, has invariably led to the cessation of treatment, at any rate for the time being, with the result that further signs of renal failure have not occurred. Pre-existing renal disease has been regarded either as a contra-indication to treatment or as an indication for small dosage, according to the severity of the disease. Massive doses, however, have led to the appearance of other symptoms which appear to be due to renal damage. These are pain in the back, hæmaturia, drowsiness, headache, and vomiting. Headache and vomiting, however, may occur without other evidence of renal failure.

Changes in the Blood-urea.—Routine estimations have been made of the urea content and in a few cases of the non-protein nitrogen of the blood. The results obtained seem to indicate that small doses of lead are without effect on the value of the blood-urea. Massive doses of lead almost invariably cause a rise in blood-urea, often a marked rise. There is, however, always a subsequent tendency to fall after a few days. With the rise in blood-urea there is a simultaneous fall in the excretion of total urea. (Table VI.)

Changes in the Urea-concentrating Power of the Kidney.—The urea-concentration test becomes inapplicable of necessity in cases in which there is marked suppression of urine. It is, therefore, of very little value in determining the degree of renal impairment following a massive dose. It was used, however, in one such case after the immediate effects of the lead had passed away. No change in the concentrating power occurred at this period. In respect of smaller doses of lead there were also no definite changes. (Table VII.)

Changes in the Urine.—Diminution in secretion often precedes the appearance of albumin in the urine following lead therapy, and is a valuable indication of early renal damage. It occurs occasionally during the administration of small doses and almost invariably after massive doses.

The quantity of lead administered in several small doses at intervals necessary to produce albuminuria varied from 0·06 g. to 0·83 g. Massive doses (0·1 g.) invariably produce it at once. The albuminuria usually disappears if no further injections are given. This condition has occurred in 43 (23 per cent.) of the cases treated. The total amount of lead necessary to produce it was less than 0·1 g. in six cases, between 0·1 g. and 0·2 g. in 23 cases, between 0·2 g. and 0·3 g. in 6 cases, and over 0·3 g. in 6 cases.

Casts appeared in all cases treated by massive doses but eventually disappeared in most. On one occasion granular and hyaline casts did not appear until 17 days after the injection of 0·15 g., to disappear again subsequently. It was unusual to find them after smaller doses.

The quantity of chlorides in the urine is unaltered, as a rule, after small doses of lead, but these salts may be completely absent for a time after large doses.

Pathological Changes in the Kidney.—The kidneys of two cases which had received massive doses of lead showed little macroscopic changes at autopsy, apart from congestion. Microscopically, very definite changes were found affecting mainly the secreting tubules.

CASE 28c (Epithelioma of face).—P.M.:—Kidneys: Acute congestion. Considerable amount of advanced cloudy swelling, three-quarters of the epithelium being affected in the tubules. A few isolated areas of chronic interstitial nephritis. No definite endarteritis. (Total amount of lead = 0·35 g., including a massive dose, 0·1 g.).

CASE 29c (see Fig. 4) (Sarcoma of femur).—P.M.:—Kidneys: Moderate amount of cloudy swelling and considerable dilatation of secreting tubules producing an appearance similar to that met with in subacute diffuse nephritis. No casts or other evidence of acute nephritis. Arteries apparently normal. (Total amount of lead = 0·34 g., including a massive dose, 0·1 g.)

The kidneys of three dogs with spontaneous malignant tumours that had received varying doses of lead were also investigated.

Dog, "Major"; mongrel. Kidneys: Cloudy swelling of the secreting tubules. No arterial changes. (Total amount of lead = 0·0612 g.)

Dog, collie (male). Kidneys: Acute congestion and tubular necrosis. (Total amount of lead = 0·2 g.)

Dog, "Pat"; Irish terrier (male). Kidneys: Tubular necrosis. Acute congestion. Thrombi in the glomeruli. (Total amount of lead = 0·0942 g.)

It is interesting to compare these findings with the appearances seen in a case of industrial lead poisoning. Tubular necrosis was found together with evidence of long-standing chronic interstitial nephritis without much glomerular change. There was a definite deposit of pigment.

THE LIVER.

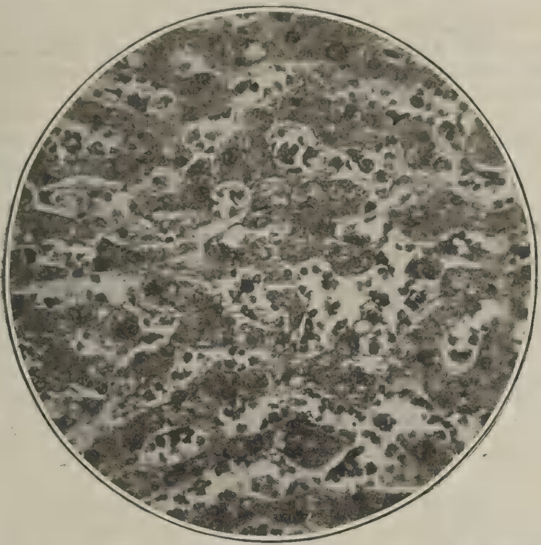
It is possible that some of the symptoms following the intravenous injection of lead—viz., headache, rigors, nausea, and vomiting—are due to impairment of hepatic function. In all cases of general poisoning the liver is the first line of defence, and it absorbs much of the toxic agent from the blood-stream. This has been shown to be the case after the administration of the arsenobenzol derivatives.

The effect of lead on the liver has been studied from two main points of view: (1) The effect on the bile-producing function; and (2) the pathological changes produced in the liver.

Effect on the Bile-producing Function.—All degrees of jaundice have been encountered varying from a slight icteric tinge of the sclerotics after the smaller doses to a deep tint of the skin with a large amount of bile in the urine, which is often seen after massive doses. It is probable that the lesser degrees of jaundice are purely hæmolytic in origin. This is supported by the fact that in these cases, while no bile is to be found in the urine, there is often excess of urobilin, and the Van den Bergh reaction of the blood serum is indirectly positive only.

An explanation of these phenomena would seem to lie in the fact that lead influences the bile-producing mechanism just like phosphorus, arseniureted hydrogen, and toluylene diamine, partly through blood destruction and partly through its direct effect on the bile-secreting cells of the liver. In the slight cases the bile-secreting cells are probably unaffected, and the jaundice is due to the excessive production of bile-pigments from the products of hæmolysis by the Kupffer cells. These pigments are produced in too large a quantity to be taken up entirely and secreted by the liver cells, with the result that a quantity continues to circulate in the blood, and slight jaundice follows—a similar state to that which occurs in pernicious anæmia and acholuric jaundice.

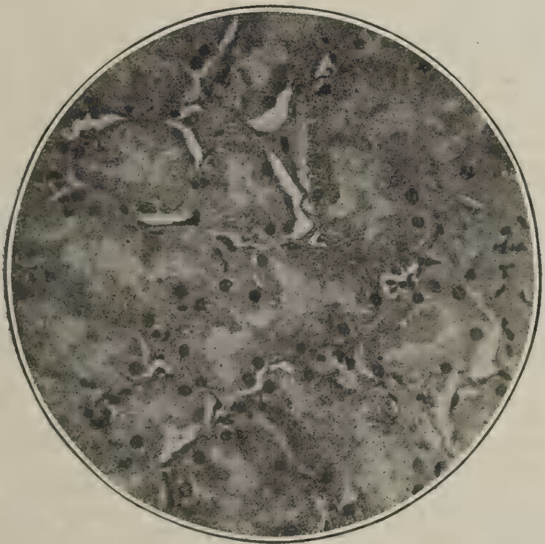
FIG. 1.



CASE 28C.—Section of liver showing congestion, slight fatty infiltration, hæmosiderin. × 300.

In other cases, especially when massive doses have been administered, it appears that, in addition to damage and disordered function of the polygonal cells, there is also obstruction in the smaller bile-ducts due to cholangitis. The jaundice is deep; bile appears in the urine, and an immediate direct Van der Bergh reaction is the rule.

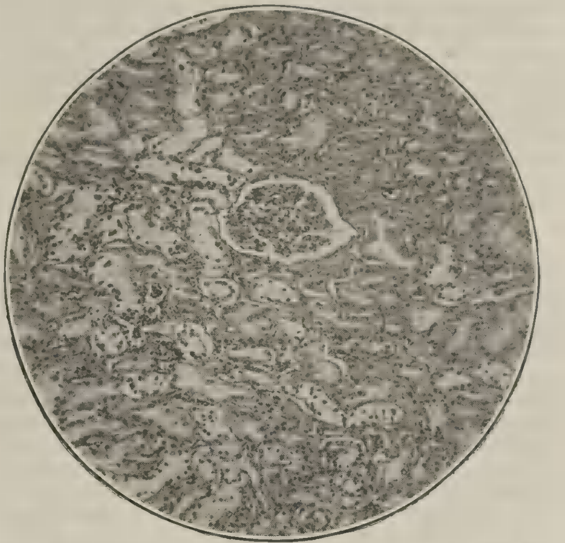
FIG. 3.



The same as Fig. 2. × 300.

Pathological Changes Produced in the Liver.—The pathological changes produced by lead were studied in the material obtained at autopsies on two human subjects and two dogs. The outstanding changes appeared to be: fatty infiltration, congestion, and the deposit of hæmosiderin.

FIG. 2.



CASE 28C.—Section of kidney showing advanced cloudy swelling of tubules. × 75.

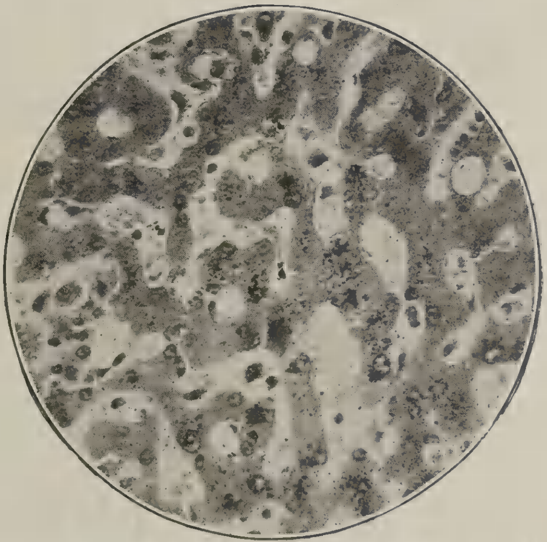
CASE 28C (Epithelioma of face).—Liver: Congestion and small deposit of hæmosiderin. (Total lead = 0·35 g.)

CASE 29C (Sarcoma of femur).—Liver: Fatty infiltration. Deposit of hæmosiderin in the liver cells and Kupfer cells. (Total lead = 0·34 g.)

Dog; "Major." Liver: Fatty infiltration. (Total lead = 0·0612 g.)

Dog, collie. Liver: Marked congestion. Fatty infiltration. (Total lead = 0·2 g.)

FIG. 4.



CASE 29C.—Section of liver showing hæmosiderin. × 300.

Similar changes were found in a case of industrial lead poisoning, where the main features were: fatty infiltration and the deposit of pigment.

It is only right to point out that with increased experience we now find it possible to avoid all the more serious toxic effects of the administration of lead, although it is only to be expected that those of a less serious nature, such as nausea and colic, will occasionally be seen. The foregoing account of the poisonous effects of lead may, indeed, be taken as demonstrating the difficulties through which we have had to fight our way to reach comparative safety. This we believe we have accomplished. At the same time it must be emphasised that only long experience, careful judgment, and complete biochemical investigations have enabled us to secure our patients from harm. Such immunity as we have established in this respect can only be attained by those using this form of treatment if they obtain first-hand knowledge of the method and carefully follow the suggestions made in our next communication on the treatment of patients.

General Summary and Conclusions.

Blood Changes.

1. Lead causes changes in the red cells. There is punctate basophilia, which may appear within a few hours of initial dose. Anæmia and its accompaniments, polychromasia, anisocytosis, and poikilocytosis occur later. This anæmia may be only temporary, or, if bone-marrow be involved, may persist.
2. Leucocytosis has frequently been observed, especially when the blood has been examined shortly after an intravenous administration of lead. Leucopenia occurs occasionally. Neither of these phenomena appears to be constant.
3. A slight relative lymphocytosis may occur, but this is not generally marked.
4. There is a definite increase in the number of granular forms of leucocytes.
5. Anæmia is a consequence of the long-continued administration of lead, and it is accompanied by the usual symptoms of that condition—namely, headache, lassitude, and palpitation. In women there may be amenorrhœa. This last-named is not constant, and depends on many circumstances.

Alimentary System.

1. Blue line at the gum edge is rarely seen when lead is administered intravenously.
2. Nausea and vomiting appear to be dependent on the amount of lead administered, but occur after a smaller total quantity when given in massive doses, rather than after the long-continued administration of small doses.
3. Intestinal colic occurs with considerable frequency after the administration of massive doses; it is not seen after the long-continued administration of a smaller quantity of lead.
4. Constipation and diarrhœa have not been observed as definite phenomena supervening under the treatment adopted.

Nervous System, including the Retina.

1. Psychopathies may occur after the intravenous administration of lead; they are, however, rare.
2. Neuropathies do not occur when lead is administered in the manner mentioned.
3. The retina may be affected; in these circumstances it is probable that it is a concomitant of renal involvement.

The Kidney.

1. The toxic effect of lead on the kidney as the result of intravenous therapy is sufficiently frequent and of such magnitude as to require the greatest caution in the administration of this drug, especially in large doses.
2. The functional impairment caused by many small doses is smaller in degree but more permanent than that caused by occasional large doses.
3. The earliest indications of renal failure appear to be: (*a*) Diminution in the quantity of urine secreted; (*b*) the presence of albuminuria; and (*c*) the presence of œdema.
4. A rise in blood-urea does not occur, as a rule, until the damage is sufficiently great to be detected clinically. Changes sufficiently great to be of value have not been observed in the urea-concentrating power of the kidney.
5. As in nephropathies due to other causes, it is difficult to correlate functional impairment with pathological change. A case which showed advanced cloudy swelling in three-quarters of the tubules has good renal efficiency as determined by the usual tests.

The Liver.

Pathological changes are not so marked in the liver as in the kidney, and the main impairment of function seems to be connected with the bile-producing mechanism.

General.

The administration of lead is a form of treatment that should never be attempted by those who have not complete laboratory facilities at their disposal, and who have not studied for some time the actual treatment of patients.

We wish to acknowledge with gratitude the large amount of work done by Mr. H. F. Woolfenden and Mr. Patterson in our earlier investigations of the effects of lead.

GASTRO-JEJUNAL ULCER.*

By A. J. WALTON, M.S. Lond., F.R.C.S. Eng.,
SURGEON, LONDON HOSPITAL.

Although gastro-enterostomy has been performed for the treatment of gastric ulcers for nearly 45 years, there is still some doubt as to its value. This doubt is largely due to the fear of the later onset of gastro-jejunal ulcer. Some surgeons are advocating the use of more severe operations to prevent what they regard as a common complication; others believe that the frequency of these marginal ulcers has been much exaggerated and their danger will be outweighed by the increased risk of the larger operation. The time is therefore opportune for a careful review of the known facts which are based upon the large number of figures now available.

Frequency of Gastro-jejunal Ulcer.

The real frequency of the condition must be accurately determined, for it is possible that it is believed to be common owing to the fact that only the failures present themselves for further observation and treatment, while the successes are overlooked. Such an investigation is not, however, without difficulty, for there is no question but that the incidence is increased by want of technical skill in performing the operation. To-day operations of this magnitude are being widely performed by those who have only had a small amount of experience in war surgery, and who, when confronted with an upper abdominal lesion, perform a gastro-enterostomy incorrectly, or, what is of greater importance, perform it when it is not indicated. A high percentage of bad results under such conditions is to be expected, and unfortunately they discredit the operation even when it is correctly performed. On the other hand, unless all the cases are seen in an adequate follow-up department, many examples of this complication may be overlooked and the incidence placed too low. In Paterson's [12] original paper stress was laid upon the difficulty of obtaining true figures, but he found three cases in 348 patients, that is, a little under 1 per cent. Judd[8] reported 54 in 3324 gastro-enterostomies, that is, 1·04 per cent. Lewisohn,[9] on the other hand, has reported an astonishing series of 68 cases, 23 of which developed gastro-jejunal ulcers, a percentage of 34. Generally, however, there is a remarkable unanimity among surgeons of wide experience in placing the frequency between 1 and 2 per cent. My own experience is as follows:—

There have come under my care 20 cases of gastro-jejunal ulcer, 11 of them being cases upon whom I had personally operated. It is almost certain that these 11 are the total number, for all cases have been carefully watched in a most satisfactory follow-up department, and I do not think that any with this complication have escaped observation. These 11 occurred in a total of 783 gastric and duodenal ulcers which had been subjected to operation, giving a percentage of 1·4 (Table I.). Of these cases, however, a gastro-enterostomy was alone performed in 631 cases, so that the danger of this ulcer formation after simple gastro-enterostomy may from this group be estimated at 1·7 per cent. My figures, however, show that the lesion is only common after duodenal and pyloric ulcers; in fact, of the 11 cases only one occurred after a lesser curve ulcer. If, therefore, we consider the pyloric and duodenal ulcers alone, that is the group that is most favourably placed for the onset of this complication, we find there are ten anastomotic ulcers in 417 cases, a percentage of 2·4, which may be regarded as the highest incidence. It must, however, be remembered that for so crippling and dangerous a disease as an ulcer at or about the pylorus a gastro-enterostomy gives us, as I have elsewhere shown,[17] 90 per cent. of complete cures, results which are incomparably better than after any form of medical treatment. The operation must not, therefore, be condemned because so small a percentage is left with this dangerous complication, and before substituting for it any other form of operative procedure, we must be confident that this procedure does prevent the incidence of this disease, and has not a higher mortality than that of simple gastro-enterostomy, which is well under 1 per cent.

---

*A paper read before the American Inter-State Congress in London.

TABLE I.—*Frequency of Gastro-jejunal Ulcer.*

Gastro-enterostomy alone	631	11	1·7
Pyloric and duodenal alone	417	10	2·4

Ætiology and Pathology in Relation to Prevention.

There are, however, certain points in the ætiology and pathology of this condition which will indicate how its onset can be prevented. As a general rule the jejunum is remarkably free from ulceration, and is generally only affected after an artificial anastomosis has been made between it and the stomach. Von Roozer[16] in reporting three cases first suggested the possibility of primary ulceration in this position, and Richardson, in reporting two of his own cases, was able to collect ten others from the literature. I[17] have reported another similar case occurring in a woman. After gastro-enterostomy the ulceration always occurs in proximity to the junction, and although gastro-jejunal and jejunal ulcers have been described, I have never yet seen a true example of the latter. In every case which I have had the opportunity of observing there has been evidence that the ulcer has started directly at the junction, for even when the ulcer was relatively remote there was a scar extending to the anastomotic line.

The ulcers are nearly always found after an operation for a pyloric or duodenal ulcer. This relationship has been constantly found by all observers, and it will be noted in my own series of 20 that there was only one unusual case in which the ulcer followed a lesion of the lesser curve. It is also almost wholly limited to males, possibly because they are so much more liable to ulcers at the pylorus and in the first part of the duodenum. In my own series of 417 pyloric and duodenal ulcers, 344 occurred in males, and of the 20 gastro-jejunal ulcers only one was a female (Table II.), and in her case there were exceptional conditions. It is said never to follow an operation for carcinoma of the stomach, although I know of one such in the literature which was reported by Lennander.

TABLE II.—*Distribution of Gastro-jejunal Ulcers.*

Ulcers.	Total.	Males.	Females.	Gastro-jejunal ulcers.
Lesser curve ..	366	228	138	1
Duodenal and pyloric	417	344	73	19
Gastro-jejunal ..	20	19	1	—

The ulcers, as seen shortly after the gastro-enterostomy, may be acute, shallow and irregular in outline, and usually involve one-third or so of the circumference of the new opening. The floor may be covered with sloughing material, and may be the site of a considerable amount of hæmorrhage. If seen later they have all the characters of a chronic peptic ulcer and deeply penetrate the walls at the junction. If they become adherent to the colon the penetration may give rise to a gastro-jejunal colic fistula; if non-adherent, perforation leads to a diffuse peritonitis. A few may penetrate anteriorly, and becoming adherent to the abdominal wall lead to a local abscess. It has been thought that the ulceration owes its inception to the trauma of clamps applied to the jejunum during the operation. This is, however, improbable, since the ulcer nearly always commences, not in the jejunum, but at the line of suture, and the complication seems to be as common whether the anastomosis be performed with or without the use of clamps. The experiments of Gronnerund[3] showed that in dogs the use of clamps made no difference to the incidence of gastro-jejunal ulceration.

Occasionally acute ulceration at the junction is found when the patient has suffered from some acute infective condition immediately following the operation, and hence it is probable that such an infection may be a predisposing factor. It cannot, however, be the only one, nor indeed the most important one, for in many cases the patient has made an uninterrupted recovery from the gastro-enterostomy.

Technical Errors in the Primary Operation.

Technical errors in the performance of the primary operation are unquestionably an important factor; the ulcers, for instance, are found much more commonly after the use of Murphy's button, as is, indeed, to be expected, for this device has to separate by a process of sloughing at the edges of the anastomosis which is likely to progress to chronic ulceration. In the same way the use of silk sutures appears to be a definite factor, for a large number of such ulcers have been reported where a portion of silk was found hanging from the base of the ulcer. In my own 20 cases a portion of such suture was found in nine, so that at one time I was strongly of the opinion that this was the factor of importance. The persistence of the ulcers after the sole use of catgut sutures shows that this is not the only cause. Catgut should alone be used, as it will reduce the incidence of this complication, but it will not entirely abolish it. Another step in the technique around which much discussion has arisen is that of occlusion of the pylorus. Martin[10] points out that the pancreatic secretion is normally activated by the passage of acid through the pylorus. The contact of this acid with the duodenal mucosa produces secretin which is carried by the blood-stream to the pancreas where it stimulates the secretion of the pancreatic juice. Galpern[2] has laid stress upon the importance of this in surgery, and quotes an experiment of Popielski in support of it; a dog's stomach was divided into pyloric and cardiac halves; the introduction of acid into the cardiac end produced no flow of pancreatic secretion, but when inserted into the pyloric end the secretion was profuse. He believes that this experiment is reproduced when the pylorus is occluded. Holzweissig[6] quotes a case supporting this view. The bile and pancreatic ducts were occluded by gall-stones and caused the death of the patient. At post mortem acute ulcers were present in the first 10 cm. of the jejunum, and he believes that this was due to the fact that the acid was not neutralised in the pancreatic secretion. It is interesting to note in this respect that in my one case of gastro-jejunal ulcer occurring in a woman there was also chronic pancreatitis with obstructive jaundice, and it is possible that the absence of a pancreatic secretion was a contributory factor. Von Haberer[5] believes that occlusion of the pylorus has a very definite bearing, for he states that in his series there were 275 cases of simple gastro-enterostomy with three cases of jejunal ulcer, and 71 cases of pyloric occlusion with 12 jejunal ulcers. These views are in entire opposition to the findings of Paterson,[12] who has shown that after gastro-enterostomy there is a diminution in the total chlorides as well as in the free HCl, a change which he regards as being due to the fact that the hormone regulating the formation of HCl is formed in the pyloric portion and is not utilised if the food does not enter this portion of the stomach. Whether a permanent and complete occlusion of the pylorus has any effect on increasing the incidence of this lesion I have no evidence in my own experience to show, but my figures make it quite definite that embedding a duodenal ulcer with silk, which gives rise to a temporary occlusion, has no such effect, for not only have I not had a larger incidence of this complication, but I also carry out a similar temporary occlusion after excision of all ulcers of the lesser curve, and a gastro-jejunal ulcer here is of extreme rarity. That gross errors of technique will increase the incidence of this condition is therefore certain, but that alterations in the minor details have any bearing is improbable, for the majority of surgeons have an incidence of 2 per cent., and it is unlikely that they would all commit errors with the same frequency.

Gastro-jejunal Ulcers and the Prior Operation.

The important question, however, is whether these ulcers can occur after operations other than gastro-enterostomy. The two alternative steps which have been most frequently advocated are gastro-duodenostomy and partial gastrectomy.

Naturally enough no true gastro-jejunal ulcer can occur after a gastro-jejunostomy, but any recurrence of the ulceration at or about the site of the enlarged pyloric opening would be of a similar nature, and would have to be considered in weighing the merits of one operation against the other. Such recurrences are indeed not uncommon, and Turner[15] in his analysis of 43 cases of pyloroplasty found in four cases a recurrence with inflammatory masses near the pylorus, giving a recurrence rate of over 8 per cent., which is considerably greater than the incidence of gastro-jejunal ulcer.

It is generally tacitly assumed that a partial gastrectomy will not be followed by any gastro-jejunal ulcer, and it is on these grounds that this more extensive operation has of late been so frequently advocated as a routine line of treatment for pyloric and duodenal ulcers, and this in spite of the fact that even in the hands of skilled surgeons this operation may be, as Pannett,[11] who advocates its use, points out, a very prolonged and tedious measure which is associated with many difficulties. It is certainly the experience of the majority of surgeons that such ulceration is much less common after partial gastrectomy than after a simple gastro-enterostomy, and Sherren,[14] in 1924, states that up to that period he had never had a marginal ulcer after partial gastrectomy, and the argument has even been put forward that such ulceration is almost impossible because removal of the pyloric antrum abolishes the mechanism of the secretion of acid in the fundus glands. There have occurred in my practice two cases following partial gastrectomy by other surgeons, and others have been reported by Beer[1] and H. Haberer.[4] Von Haberer[5] has even abandoned the Billroth II. and Polya operations and returned to the Billroth I. method, as gastro-jejunal ulceration was in his experience so common after the former operations. Wright,[18] after reporting two cases of a similar nature, gives what is probably the correct explanation of the popularly accepted belief that these ulcers are rare after this operation. He states that up to the present time partial gastrectomy has usually been performed for carcinoma of the stomach, and it is only of recent years that it has been carried out for peptic ulceration, and that marginal ulceration has begun to follow its use. There is thus no doubt that this serious complication is not entirely eliminated by the substitution of the more dangerous operation of partial gastrectomy. Dr. Mayo has pointed out that the removal of so large a portion of the stomach for a small ulcer, perhaps of less than 1 cm. in diameter, in order to lessen the frequency of this rare complication, is too extensive and too dangerous a procedure. This has always been my own view, and I have been very loth to remove perhaps three-quarters of the healthy stomach for a small innocent ulcer. It is true that surgeons of wide experience are agreed that the end-results of a partial gastrectomy are extremely satisfactory, and in the 188 cases in which I have performed this operation for large ulcers and carcinoma I have never met with any severe disability. Nevertheless, Hurst[7] has laid special stress upon the late complications following gastrectomy, and has even claimed that later in life it may be followed by pernicious anæmia. He states that he knows of five such cases where this complication resulted. These claims cannot yet be considered as proved, but they strengthen the belief that so large a removal of a healthy viscus will be found in the future not to be entirely free from danger. Too much stress must not be placed upon the published statistics, for these are generally the results of surgeons of wide experience, and it is highly improbable that surgeons less skilled in abdominal surgery will be able to obtain a mortality even as low as 10 per cent., a mortality which is greater than the combined mortality of gastro-enterostomy and the incidence of gastro-jejunal ulcer after such an operation. To my mind, therefore, there can be no justification for the general substitution of partial gastrectomy for gastro-enterostomy in the treatment of pyloric and duodenal ulcers. I believe that an entirely exaggerated view has been taken of the importance and incidence of marginal ulceration after gastro-enterostomy. This complication is a very serious danger, but it only occurs in a small percentage of cases, and its incidence will not be entirely prevented by the use of an operation which carries a much higher mortality.

Acid of the Gastric Juice in Relation to Ulceration.

It is now clearly recognised that there is a close relationship between the amount of acid in the gastric juice and the incidence of gastric and duodenal ulceration. The work of many investigators, and especially that of Hurst,[7] has established the fact that with pyloric and duodenal ulcers the acidity is high, and it is after operation for these lesions that gastro-jejunal ulceration most commonly occurs. With lesser curve ulcers the acidity is lower and marginal ulceration is rare. With carcinoma, free acid is usually absent, and marginal ulceration is practically unknown. The test meals of my own cases make these facts clear. With carcinoma of the stomach there was nearly always a complete absence of free acid, and with the lesser curve ulcers it was lower than with the pyloric and duodenal ulcers (Table III.). Of the 20 cases of gastro-jejunal ulcer I was able to obtain records of the test meals previous to the first operation in my own 11 cases and in two others. In these 13, who were all males, the acidity was much above the average (Table IV.). As this series was small Mr. Cairns investigated a complete series from the London Hospital comprising 50 cases. Excluding my own cases as above, and those in which the primary operation was performed elsewhere, there were left 19 cases, the average acidity of which is shown in Table V., the figures of which are nearly identical with my own.

In the one case of lesser curve ulcer in which a marginal ulcer followed operation, the test meal showed before the primary operation free HCl 0·23, total acidity 80, and before the marginal ulcer 0·10, 40.

It seemed possible that a variation in the acidity between the different sexes might also account for the tendency of this complication to occur almost entirely in males. I therefore investigated the figures of my series, and it is clear from an inspection of Table VI. that both with the lesser curve and the pyloric and duodenal ulcers the average acidity was considerably higher in the males than in the females.

TABLE III.—*Acidity with Different Types of Ulcer.*

Ulcers.	Cases examined.	Average total acid.	Average free HCl.
Lesser curve ..	192	58	0·118
Duodenal and pyloric	257	62·5	0·160

TABLE IV.—*Acidity with Gastro-Jejunal Ulcer.*

Gastro-jejunal ..	13	71	0·18

TABLE V.—*Acidity with Gastro-Jejunal Ulcers* (Mr. Cairns).

Gastro-jejunal ..	19 all males.	68	0·18

TABLE VI.—*Acidity in the Two Sexes.*

Lesser curve—			
Males	135	61	0·123
Females	57	51	0·108
Pyloric and duodenal—			
Males	213	63·5	0·165
Females	44	57·6	0·136

Up to a short while ago it was usually accepted that the effect of gastro-enterostomy for a pyloric or duodenal ulcer was in the greater number of cases to enormously decrease or entirely abolish the amount of free acid which occurred in the test meal. More recent observations have tended to throw doubt on these conclusions. Therefore Mr. Cairns collected and examined for me a considerable series of more recent cases at the London Hospital, where observations on the acidity had been carried out both before and after gastro-enterostomy. The cases occurring in the years 1921–24 were taken and included 51 lesser curve ulcers and 115 pyloric and duodenal ulcers. Of these, nine of the lesser curve and two of the pyloric ulcers had no free acid previous to the operation and are therefore excluded. The changes occurring in the remainder are seen (Table VII.). It will be noticed that whereas in nearly three-quarters of the gastric ulcers the free acid is abolished after operation, this change occurs in rather less than half of the duodenal ulcers. It is very probable that this difference is due to the tendency to place the stoma nearer the pylorus with the pyloric and duodenal ulcers than with those on the lesser curve, and thus to bring about a less efficient neutralisation. In my group of 13 gastro-jejunal ulcers in which test meals had been taken before and after the gastro-enterostomy, the effects were even less marked. The average acidity as contrasted with Table IV. had fallen (Table VIII.), but the numbers to be benefited were below the average (Table IX.). It is possible that the failure of the acid to fall in these gastro-jejunal ulcer cases may be due to an anatomical variation, the acid-producing cells in a certain number of duodenal ulcer cases (about 2 per cent.) being more widely distributed over the gastric surface, and thus being less affected by the gastro-enterostomy, but whatever may be the cause there is no doubt that the ulceration is dependent upon the higher acidity which occurs in the pyloric and duodenal ulcers in males, and which tends to persist after gastro-enterostomy for the latter group of ulcers.

Gastro-jejunal	13	3	[illegible]	5	3

Course of Events after Prior Operation.

It is usually accepted that the majority of cases of gastro-jejunal ulcer do not seek treatment until a considerable period has elapsed after the gastro-enterostomy, and in the ordinary course of events it will generally be found that a patient returns to hospital or to his surgeon complaining of disability some three or four years after the operation. In many published cases, indeed, the interval has been much longer than this, and has extended to 10 or 15 years, so that this free interval is often quoted as being characteristic of the disease. One thing has, however, very clearly emerged from my periodical examination of these cases in a follow-up department, and that is that they never make the same complete and absolute recovery after the gastro-enterostomy which is so characteristic of the greater majority of duodenal and pyloric ulcers. They will often state that they are very much better and have been enormously improved, but if they are cross-examined it will be found that they are unable to take full diet, or that they have a little feeling of discomfort coming on late after food which necessitates their taking a dose of bismuth and alkali through a prolonged period after the operation. It will be noted, too, that although these symptoms are so slight there is a certain periodicity about them. They may continue for a month or two after the operation and then be considerably relieved for several weeks, only to return again. This change is very distinct from the usual patient who states that he is perfectly well, is able to eat anything, and has never been so well in his life. As they are watched from month to month it will be noticed that they develop a more definite periodicity, their symptoms become more marked, and especially does the pain become more severe. By keeping a careful record in this way it will often be noticed that when their symptoms have been established they will state that they have been quite well after the operation for a prolonged period, having in the meantime entirely forgotten the minor symptoms. By such a method of careful following it is possible to get evidence of these ulcers in their earlier stage, and I think it is the use of such a department which explains the fact that I have never yet seen a perforation of one of these ulcers either into the general peritoneal cavity or into the colon; complications, which from the published statistics, appear to be relatively common. When the disease is well established the severe symptoms show a periodicity which is nearly as characteristic as that of a duodenal ulcer. They appear in attacks which will last from three to four weeks, and may then be followed by several months of complete relief. If the base of the ulcer becomes adherent to the surrounding tissues, most frequently the transverse colon and the mesocolon, the symptoms will tend to become much more constant. The pain shows characters which in the greater part are similar to those of a duodenal ulcer; that is to say, it comes on late after the ingestion of food, will often wake the patient at night, and nearly always is relieved for the time being by taking more food. It differs, however, in one respect: it radiates more widely, and especially does it pass down to the left iliac fossa. It is often described as agonising and severe, and at first when the ulcer is non-adherent is relieved by alkalies. Later, if the transverse colon is involved, practically no relief is gained by this means. It is interesting to note that in the majority the attacks of severe pain are associated with vomiting, an indication that the stomach is involved as well as the jejunum. Generally a considerable amount of relief is given by the vomiting, which nearly always contains a large amount of bile. As a rule, hæmorrhage is not a marked feature, but there are cases where it is predominant, and I have two cases in my series in which the presence of repeated hæmorrhages, which had reduced the patient to a considerable degree of anæmia, were the only evidence that ulceration existed. In such cases the ulceration is usually much more superficial, and the absence of pain is accounted for by the fact that the deeper tissues are not involved. Generally the test meal shows the presence of a considerable amount of free acid, the reduction by the gastro-enterostomy having been very incomplete. In three of my cases, however, there was a complete absence of free HCl. The X ray evidence is usually of great value. In the long-standing cases direct evidence will be obtained, for the outline of a penetrating ulcer may be easily visible, or after the meal has passed from the stomach a meniscus may be left in the region of the stoma. In the earlier and more shallow ulcers the evidence will not be so definite and may chiefly consist of hyperperistalsis and irregular contractions of the stomach and duodenum. Direct evidence of some alteration in the outline of the stoma was obtained in 12 of my cases.

Treatment after Ulceration has Occurred.

If once ulceration has occurred, and there are definite symptoms or a positive X ray examination, operative interference is the only treatment that is likely to be of any value, but in the earlier stages, when there are simply ill-defined symptoms, a course of medical treatment may possibly prevent the progress of the ulcer, and it is in order to obtain the cases in this stage that a series of follow-up investigations is of extreme value. As regards the preventive treatment of the first operation it has been pointed out already that one of the factors of importance is the abolition of all mechanical devices to perform the anastomosis and the use of catgut sutures throughout. In addition, extreme care must be taken to bring about absolute apposition of the mucous coat, for if a gap be left the deeper layer of sutures will be exposed, and although of catgut they may persist for a long time and act as foreign bodies. For this reason I have abandoned the excision of the strip of mucous membrane surrounding the opening, although this method gives a much neater union. Another factor which I think will be of value, and which I am now adopting, is to place the anastomotic opening rather higher up on the greater curve, that is, about 3 in. from the pylorus. There was a tendency among all surgeons in the past to make the opening as near to the pylorus as possible, but it has been clearly shown that in ulcers of the lesser curve, where the opening has been placed high up, the results have been satisfactory, and as a general rule the higher the opening is placed the more complete is the neutralisation of acid. I was formerly of the opinion that, in the treatment of the established condition, excision of the ulcer and resuturing with catgut alone would often give rise to a cure; further experience has, however, shown that this method is unsatisfactory. Where it was adopted I have had four cases of recurrence, and I believe that the only treatment which is likely to be of any avail is to perform a partial gastrectomy which is sufficiently extensive to considerably reduce the acid. This may be one of the most difficult operations in modern surgery, especially if the primary operation has actually been of the no-loop variety. If the opening is placed 1–2 in. distal to the flexure the operation is comparatively easy, and it is now, therefore, my custom in all cases of pyloric and duodenal ulcers in which the acid in the test meal is abnormally high not to perform an absolute no-loop gastro-enterostomy, but to place the opening about 2 in. from the flexure. I have never found any evil consequences follow this step, and I believe that we have been obsessed with the idea of the value of no-loop anastomosis owing to the evil effects which unquestionably follow the use of very long loops. The division of the stomach should be made well proximal to the anastomosis, and if sufficient of the stomach is taken away it is almost certain that the acid will be reduced; that is to say, the method which one would advocate is to perform a simple gastro-enterostomy with the opening rather higher than usual and rather further from the flexure as the routine treatment for pyloric and duodenal ulcers, and to reserve the more extensive and dangerous operation of partial gastrectomy for the small number of cases that develop gastro-jejunal ulceration. Although the partial gastrectomy for these ulcerative cases is undoubtedly a severe operation, most of the patients stand it remarkably well. In my own series of cases it has been performed 13 times, and 11 cases have made a complete recovery, and after the partial gastrectomy have remained entirely free from symptoms. The question will naturally arise, if partial gastrectomy is unsatisfactory as a primary method of treatment, why should it be selected as the method of choice after the ulcer is definitely established? The answer to this is that the liability for secondary ulceration will probably depend upon the amount of stomach which is removed, so that if a partial gastrectomy is performed at the primary operation it will have to be extensive, and will carry a high mortality, and so big and extensive an operation should be reserved for the small number of cases that have definitely developed this complication.

Conclusions.

(1) Gastro-jejunal ulcer is a relatively rare complication of gastric and duodenal ulcer occurring in a little over 2 per cent. (2) Its frequency does not warrant the introduction of extensive operations for the treatment of the primary condition. (3) It is almost entirely limited to pyloric and duodenal ulcers. (4) It occurs almost wholly in the male sex, and is found in those cases in which the gastric acidity is high. (5) As a general rule it is found when the acidity after the primary gastro-enterostomy persists, this being possibly due to an anatomical variation in the distribution of the oxyntic cells in the stomach. (6) The symptoms of this complication, although slight at first, nearly always commence immediately after the primary operation. (7) The frequency of the condition will probably be diminished by performing the anastomosis rather higher up than usual. (8) The treatment of the established condition should be by partial gastrectomy, which will be aided by placing the stoma rather more remote from the flexure than is usual at the first operation.

THE VALUE OF SOFT-RAY TECHNIQUE IN PULMONARY RADIOGRAPHY.

BY BERNARD HUDSON, M.D. CAMB.,
M.R.C.P. LOND., S.F.D.,
VICTORIA SANATORIUM, DAVOS-PLATZ, SWITZERLAND ;

AND

PERCY G. SUTTON, M.S.R.,
MEMBER OF RONTGEN SOCIETY ; RADIOGRAPHER, X RAY INSTITUTE, DAVOS-PLATZ, SWITZERLAND.

THIS article is an attempt on the part of the writers to explain the value of the soft-ray technique of radiography,[1] especially as a diagnostic aid in dealing with early tuberculous lesions of the lungs. A radiograph of a lung affected with tuberculosis may be made to show a very different picture, according to the quality of the rays employed. The hard ray will penetrate an early focus of tubercle and give an appearance similar to that of normal tissue. Old fibrotic foci, however, are opaque to the more penetrating, and in fact, to all rays. The hard-ray radiograph is liable to show the older and healed lesions only, the more recent and much more important earlier foci being generally missed. In order to obtain really satisfactory results in pulmonary radiography, soft-ray technique must be employed.

Comparison of Techniques.

The appearance of a normal healthy chest in an adult taken by hard-ray technique varies enormously from the same subject taken by soft rays. Using the hard ray, the fine mottling of the connective and interstitial tissue of the lung is not shown, and the harder the ray the less this is discernible. All that is seen in the negative is a more or less uniform darkness over the whole of both lungs, with the ribs showing very plainly, even the bony markings being visible ; the vertebral column, too, is often plainly distinguished through the heart shadow. The roots of the lungs appear as lighter shadows on each side, but their finer parts are not seen, nor are the delicate radiations which extend downwards, upwards, and outwards from them. This appearance, of course, varies with the hardness of the ray employed, the harder the ray the more easily does it penetrate the interstitial tissue of the lungs.

The appearance of the same chest taken by the soft-ray technique is very different. Scattered through the lungs on both sides there is seen a fine mottled and striated appearance, which is the pulmonary connective and interstitial tissue, the roots are much better defined, and their radiations plainly seen. The ribs appear as more or less indefinite shadows, and the fine bony markings on them are not evident. The details of the vertebral column are not seen, as the soft ray does not penetrate the heart and pericardium.

Comparing these two radiographs, the uninitiated would perhaps say that the one taken with the hard ray was the better picture of the two, and the one taken by the soft ray might perhaps be diagnosed as tuberculosis affecting the roots of the lungs, the mottling being also thought to be pathological in appearance. These characteristics are even more distinct in children ; and in children of, say, about 8 to 10 years old the diagnosis of hilum tubercle has no doubt often been made from the appearance of a soft-ray radiograph of a normal chest of a child. It is a very important thing, when giving an opinion of a chest radiograph, to be able to distinguish what is normal from what is beginning to depart from the normal, which can only be done by an extensive experience of the soft-ray technique.

We might here mention that, in our opinion, it is extremely important that the radiologist should mark on the radiograph the conditions under which it was taken—i.e., penetration of tube, milliamperage, focal distance, exposure, &c. To resume, by using the hard-ray technique an excellent picture of the bones of the chest is obtained, but the finer details of the lung tissue missed.

In THE LANCET of March 17th, 1925, the present writers, in a paper entitled X Ray Examination of the Chest, discussed the value of X rays in the detection of pulmonary tuberculosis, and stated that, in their experience, they had come across several cases where physical signs were absent on clinical examination, but which showed, on X ray examination, signs of tubercle such as enlarged glands, and masses of infiltration round the hila, lesions which could not be made out with any degree of certainty by clinical means. They are now prepared to go even further than this, and to state that a recent pulmonary lesion in an early case, or a new focus in an old case, may be detected by the soft-ray technique, before definite physical signs have made their appearance. The old hard-ray method was of no use whatever as a diagnostic aid in early pulmonary tubercle ; it showed up the old fibrosing lesions perfectly well, but penetrated and completely missed the early infiltrations, which latter are revealed by means of the soft-ray technique, as fluffy, indefinite, cotton-wool-like shadows. It was because of the general use of the hard rays in former years that X ray examination, as an aid to diagnosis in tubercle of the lungs, fell into disrepute. It is still, we believe, very commonly stated that tuberculosis of the lungs which cannot be discovered by careful clinical methods will not be discovered by X ray examination, either fluoroscopic or radiographic. This, we beg to submit, is certainly not always the case, and in every suspected case of pulmonary tuberculosis, whether it is an early new case or a suspected reinfection in an old case, competent X ray examination should be performed as a matter of routine, using the soft rays, the technique of which is given below.

Correct Technique of Chest Radiography.

Before discussing the correct technique of chest radiography, we might mention that, in our opinion, the following accessories are necessary to the radiologist : 1. Kilovoltmeter. This instrument saves the time and trouble of taking readings by equivalent spark gap, penetrometer, &c. 2. A reliable milliampermeter. 3. An automatic time switch.

Technique.—The following standardised technique has been adopted by the writers : Kodak duplitised films between two intensifying screens ; distance between anticathode and film, 1 metre ; secondary voltage, 45 kilovolts ; milliamperage, 40 ; exposure, $\frac{1}{2}$ to 1 second, according to the thickness of the subject, the double focus Coolidge tube being employed.

Standardisation of Technique.—In chest radiography it is important that the technique be standardised, as when a case comes for re-examination it is useless to compare the two radiographs, if the first one has been taken under one set of conditions, and the second one under another. In this respect the Coolidge tube and high-tension transformer are

---

[1] By soft rays we mean a secondary voltage of 45 kilovolts = an equivalent spark gap of about 4 inches = 4 benoist. By hard rays a secondary voltage of 60 to 70 kilovolts = an equivalent spark gap of about 6 inches = 6 to 7 benoist.

invaluable, as the current passing through the tube and the penetrating power of the rays are independent of each other. If the auto-transformer rheostat is adjusted to give a certain secondary voltage, the penetration of the tube remains constant no matter whether 4 or 40 milliamperes are passing through the tube. An X ray journal should always be kept, and in it noted the conditions under which the radiograph is taken, so that if a patient comes for re-examination, the conditions under which the first radiograph was made can be duplicated. For example, patient A. B. was radiographed six months previously, and is referred by his specialist for re-examination, reference is made to the X ray journal, and it is noted that the previous entry reads: "Focal distance, 1 metre; penetration, 45 kilovolts; milliamperes, 40; exposures, 0·75 second"; Procedure: The auto-transformer rheostat is advanced until the kilovoltmeter shows a secondary voltage of 45 kilovolts; the rheostat controlling the heating current of the Coolidge tube adjusted until the milliampermeter shows that the tube is drawing 40 milliamperes, and the automatic time switch set for 0·75 second. The exposure is then made. In this way the radiologist is absolutely certain of having duplicated the technique of the previous radiograph. Development of the film must also be standardised, the usual method being to develop the film for five minutes at a temperature of 65° F.

A NOTE ON

CHRONIC ENDOCERVICITIS:

THE END-RESULTS OF OPERATION.

BY JOHN WILLIAM BURNS, M.D. DUB., F.R.C.S. EDIN.,
HON. SURGEON, LIVERPOOL SAMARITAN HOSPITAL FOR WOMEN; HON. ASSISTANT SURGEON, LIVERPOOL MATERNITY HOSPITAL.

IN 1922 I read an article[1] on chronic endocervicitis and its treatment before the North of England Obstetrical and Gynæcological Society, in which I stated my belief that the best way of dealing satisfactorily with cases of chronic endocervicitis, especially those associated with erosion, was to remove the eroded area along with the lower half or two-thirds of the cervical canal—i.e., the infected portion.

One of the main criticisms aimed at the particular type of operation which I had adopted was that it would probably have a very serious effect upon subsequent conception, pregnancy, and labour.

Technique of Operation.

Before dealing with the end-results I would like to refer to the operative procedure adopted in these cases. It is that devised by Sturmdorff, of New York, and described by Matthews.[2] The eroded area of the cervix is encircled by an incision which penetrates the vaginal covering of the cervix only. The area within the incision is seized with vulsella and pulled strongly downwards. The incision is deepened in an oblique manner with a knife or sharp-pointed scissors, so as to reach the cervical canal in the region of the junction of the upper and middle thirds. By this means a cone of tissue is removed which contains the eroded area of the cervix and the infected cervical lining. Four sutures are inserted—one anterior, one posterior, and one on either side. A vaginal pack of gauze soaked in acriflavine (1:1000) left in for 24 hours is all the dressing required.

There are several little points in the technique attention to which renders the operation very easy. The cone of tissue should not be completely separated until the lateral sutures have been inserted. As soon as the cervical canal has been exposed it should be seized with strong forceps, and pulled down in order to render easy the passage of the anterior and posterior sutures. If this is not done there is a danger of wounding the bladder in front and of opening the recto-vaginal space behind. The sutures should not be tied until all four have been inserted. The needles which I find easiest to use are small fully curved bayonet-pointed, and must be fairly strong. As a rule I do not dilate the cervix or curette the uterus.

Advantages.

These are: (1) It can be modified to meet any type of cervical laceration. (2) The whole of the infected portion of the cervix is removed and as a result healing takes place rapidly and by primary union. There is, therefore, a minimum amount of scar tissue formed. (3) There is no post-operative bleeding, as the four sutures used efficiently control the four segments of the cervix. (4) The leucorrhœa, which for the most part comes from the infected portion of the cervix, is quickly reduced, and the vaginal exudation is allowed to resume its normal acid protective quality. (5) A potentially malignant area of the cervix is removed.

Results, Immediate State.

The immediate results of this operative treatment of chronic endocervicitis are excellent. The vaginal discharge and backache disappear, and also the other discomforts arising from a profuse leucorrhœa. The patient's general health rapidly improves, probably because with the removal of the infected area she is no longer absorbing toxins. Out of 92 cases operated upon in 1922 and 1923, and investigated and followed up until a recent date, only three returned to hospital complaining that they were not cured. Of these two turned out to be cases of gonorrhœal infection, while the third was a woman who, in spite of advice, would persist in frequent douching. In view of the belief that malignant disease develops in a cervix which is chronically inflamed, it is interesting to note that out of over 200 cases examined microscopically I have not found a single case of early carcinoma or epithelioma.

The effect of this operative treatment upon subsequent conception, pregnancy, and labour is shown by the following analysis of the cases operated upon during 1922 and 1923:—

Total number of cases operated upon		120
Failed to report	28	
Cases in which supravaginal hysterectomy had been performed	3	
Cases at or beyond the menopause.	5	
Unmarried	3	
Sterile..	10	
Cases of salpingo-oophoritis	6	
	55	
Total cases in which pregnancy might be expected to occur	65	

Of these 65 cases 14 became pregnant within a period varying from two months to two years following the operation, that is, 21·5 per cent. This would appear all the more satisfactory when the fact is taken into consideration that the average age of these patients at the time of operation was 35 years. Of the 14 patients who became pregnant, one became pregnant twice within two years of the operation and 13 once, thus producing 15 pregnancies—

Total pregnancies		15
Cases which went to full term	10	
Cases terminating in miscarriage	3	
Cases not yet delivered	2	

All those cases which went to full term passed through perfectly normal labours. Of these ten cases two were primiparæ, one of which miscarried over the first pregnancy, conceived again within six months, and this time the pregnancy went to full term and terminated in normal labour. While the number of cases terminating in normal labour is somewhat small to base definite conclusions upon, yet I think these results show that this particular tracheloplastic operation has very little effect upon conception, pregnancy, or labour. The fact that eight of these cases had periods of sterility varying from two to eight years preceding the operation is suggestive that the infective condition of the cervix inhibits conception.

---

[1] THE LANCET, 1922, ii., 796.

[2] Journal of Surgery, Gynæcology, and Obstetrics, March, 1921.

Conclusions.

(1) The operative treatment of chronic endocervicitis brings about a rapid and permanent cure.

(2) As the chronically inflamed portion of the cervix is removed by this method what may be a potentially malignant area is destroyed.

(3) By rapidly decreasing the cervical discharge, which is always excessive in these cases, the vaginal exudation is allowed to resume its normal acid protective quality. This is most important from a bacteriological point of view.

(4) The operative treatment described has little or no effect on conception, pregnancy, or labour.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

THE inaugural meeting of the session was held on Oct. 12th, when the new President, Sir HOLBURT J. WARING, delivered an address on

OSTEOPATHY, CHIROPRACTIC AND OTHER CULTS, AND MEDICINE.

The PRESIDENT said he had received many inquiries from medical friends as to what was the exact nature of osteopathy and chiropractic, what were the advantages to be derived from its employment, and what disadvantages and dangers were to be feared. Briefly, the so-called principles on which these cults were founded were as follows.

Osteopathy.

This was stated to be a system of treating disease without drugs, and was based on the belief or assumption that all disease was caused by some part of the human organism being out of proper adjustment or alignment, as in the case of a misplaced bone, cartilage, or ligament; or, in the case of adhesions or contractions of muscle resulting in unnatural pressure on or obstruction to a nerve or a blood- or lymph-vessel. Investigation had shown him, however, that the different practitioners of osteopathy had varying ideas as to what was comprised in the term and what were the limitations of treatment. A later definition seemed to include the use of the term "inhibition," or the relief of pain or spasm of muscles by the application of steady pressure. This cult was founded in 1873 by Dr. Andrew T. Still, in the State of Missouri. He declared that all disease was due to or dependent upon a disturbance of the nerves or blood-vessels in the different parts of the body, especially in relation to the nerves coming out from the spinal column; that disease was also due to impairments of circulation preventing vital materials reaching different parts and organs. Osteopathy was therefore regarded as a therapeutic measure for the treatment of all disease, and apparently it was a mechanical measure, consisting of making alterations in position and relations by digital pressure or manual manipulations of the supposed diseased parts. The abnormalities of the spinal column which these practitioners considered caused disease were termed "osteopathic lesions," and often they were said to be characterised by localised areas of tenderness and muscular spasm. The means of treatment adopted by the osteopath was manipulation to correct the so-called deformity or osteopathic lesion, to bring into proper apposition displaced bony surfaces, to relax muscular spasms, and to eradicate tender points.

Chiropractic.

This, said the President, had been defined as the philosophical science and art of things natural, and a system of adjusting the subluxated vertebræ of the spinal column by hand for the restoration of health. The cult was originated by a layman, D. D. Palmer, and he founded a school, bearing his name, at Davenport, Iowa, in 1895. His theory was that disease was the result of pressure upon nerves as they emerged from the spinal column, this pressure being assumed to be caused by the vertebræ being in an abnormal position. Palmer said diagnosis was not necessary for the treatment of disease; all that was needed was to relieve pressure on nerve roots. Diseases of eye and ear were treated by both osteopaths and chiropractitioners in a similar manner, even though the nerves supplying them did not come off from the spinal cord.

The President said that a number of other cults had sprung from these two, but he only mentioned one of them, naprapathy. The practitioner of naprapathy stated that the basal centres of life were all located in the medulla oblongata or basal portion of the brain, and the nearest portion of the surface of the body to the medulla was the nape of the neck, and therefore to this region the various manipulations were applied. No medicines were prescribed, and surgical instruments were declared to be unnecessary; only thumb-pressure and free rubbing with the heel or the fist. Thus all the cults mentioned based their ideas and practice on a primary dogma which was untrue. Following upon the setting up of these cults, a number of irregular medical schools had sprung up in the States, self-styled colleges. They were mostly proprietary, and run with the object of making private gain rather than supplying well-qualified practitioners of the healing art. Apparently the only essential elementary education insisted on at most of these schools was ability to read and write; laboratory instruction, in the modern acceptation of the term, did not seem to exist, and no hospital clinical facilities were available. At one of them an elementary graduate was given the degree "L. W.," and a further qualification was awarded the style "T. N.," which investigation showed to signify respectively, "Live wire" and "Top notch"! At one of the largest of these schools anatomy was taught by a lecturer who appeared never to have gone through a course of dissection of the human body, and she had no recognised diploma or degree. Here also one of the most prominent courses was one on "salesmanship." In this course, personality, personal magnetism and psychology, various forms of advertising, selling the patient and selling the services of the practitioner, were given. They taught that there was no necessity to carry out isolation for infectious disease, and declared that osteopathy was something which could not be learned from books; only by personal instruction given by a qualified osteopath. Most of the students in these schools seemed to have been drawn from among people of the poorer class who had received but little education.

The treatment by osteopaths and chiropractitioners seemed to be very similar, consisting mainly of applying the osteopathic thrust or thump. In some cases immediately after applying this thump the operator made a clicking noise with his tongue, announcing to the patient at the same time that the displacement had been reduced, but he was enjoined to take a course of the treatment to become quite well.

Dangers of these Methods.

The President said patients suffering from severe affections were liable to be seriously damaged by having these methods practised on them. In one case of appendicular abscess the forcible treatment was applied, the abscess ruptured, and the patient died. There were many cases in which these manipulations had caused acute dissemination of carcinomata and sarcomata, and he had also seen many cases of tuberculous disease of joints in which serious damage had been caused by forcible manipulation and movement. In the United States epidemics of infectious disease have been due to lack of isolation and the practitioners of these cults carrying the infection broadcast. It could be stated that these manipulations, in some diseases and abnormal conditions, did no harm, but in the majority of diseased and abnormal conditions considerable harm might be done, and in some cases the sequel was an irreparable injury. Some of the cures reported had probably been due to suggestion, others to the direct results of manipulations and the breaking down or separation of adhesions between muscles and nerves and the adjacent tissues. Patients were usually very averse to having anything rough or forcible done to them, and often, even in the presence of adhesions, the medical practitioner pandered to this and failed to carry out the obvious measures. The patient went to an osteopath, who had no such scruples, and his prestige was enhanced accordingly. Dr. F. Albee stated that he had never discovered, in all his experience, any foundation for the chiropractic theory, and, in his opinion, it was a menace to the public at large.

The Position of Osteopaths and Chiropractitioners in this Country.

In conclusion, the President pointed out that unless they possessed a medical qualification these people could only carry on their practices here as unqualified practitioners, and they were liable to prosecution for malpraxis. They were now seeking registration and recognition by Act of Parliament, desiring to be known as drugless healers, with limitations as regards practice. The speaker's own view was that our medical practice laws ought to be amended so as to place all practitioners of the healing art on the same educational level, because of the danger of the general public being deceived by a plausible theory and the making of unfounded claims; especially was this true in the case of sufferers who had grown desperate. A number of the graduates of the schools of these cults in the States had come to this country and set up practice, seeking to extend it by blatant advertisement. He thought the State should take a strong stand in protecting the health and preserving the life of the community.

Cordial thanks were tendered to the President for his address, on the proposition of Mr. **V. Warren Low**, seconded by Sir **StClair Thomson**.

Discussion.

Dr. **Des Vœux** thought quacks would continue to exist as long as the medical profession were unable to cure all ailments, and it could not be denied that on occasion a quack had "wiped the eye" of a general practitioner. He did not think it would be wise for the profession to try to discourage quackery, especially as he did not think quacks did the regular profession any harm.

Dr. **Eustace Callender** said he had seen many sad results of people going to quacks, even among people highly placed in society. He had seen three children, one after another, allowed to die of tuberculous meningitis without any steps being taken to protect them from the disease; they were only "treated" by a Christian Scientist. Such occurrences he regarded as wicked.

Mr. **J. E .H. Roberts** referred to a case of incomplete paraplegia in a man who was shot in the war. He recovered from that. Five years later he got work as a dustman, and after a short time of lifting weights of rubbish on to the dust-cart he began to get pain in his lumbar region, and this got worse. X rays showed a bony displacement, a subluxation of the second lumbar vertebra, but the bullet was harmlessly reposing in the muscle. He, the speaker, met a man who was an osteopath, a "D.O." of some place in America, and who was also a Licentiate of the Royal College of Physicians here in London, and asked him, as he said he cured subluxations of the spine, whether he could reduce it, showing him the radiograph. The answer was: "But that is a real subluxation; I should not advise you to touch that"; a decision Mr. Roberts had already arrived at. It well illustrated a mental attitude.

Mr. **V. Warren Low** did not agree with Dr. Des Vœux's eulogy of quacks, but he thought with that speaker that the medical profession should leave them alone. And he agreed that some Department of State should undertake the education of the public as to the general structure and functions of the body, so that imposition by specious claims would be rendered more difficult.

Dr. **E. G. Graham Little**, M.P., said the question of the recognition of osteopaths in this country would probably come before the House of Commons quite soon, in response to a meeting which was held in Parliament six months ago, and convened by an influential body of members who favoured osteopathy. That meeting was addressed by a qualified medical man who had forsaken the ordinary practice of medicine and had taken up osteopathic methods. The meeting was attended by all the medical members of the House at the present time, and several of them tried to obtain a hearing. After the hour's conversation by the medical man referred to, other speakers were allowed three or four minutes, and were then told that the company present did not desire any further information from the medical point of view. The resolution, submitted by the promoters, was carried. The Ministry of Health seemed to be most sympathetic to this movement, therefore the opposition must, he thought, come more from the general body of the medical profession, and some notice ought to be taken of the fact that the speaker for the meeting was himself a duly qualified medical man. The opposition should not be an official one organised by any great body, but among the profession itself.

The **President**, in a brief reply, said he thought it was the duty of every Government to protect its citizens from fraud. To recognise and allow to register practitioners of these cults in this country would mean the incursion into the ranks of healing of men with very little general education and training.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

A meeting of this Section took place on Oct. 9th, when Sir **Arnold Lawson**, the President of the Section, occupied the chair.

Penetrating Injuries of the Eye.

Mr. **J. Gray Clegg** (Manchester) initiated a discussion on this subject, his attempt being not to range over the different varieties of perforating injuries and their treatment, but to deal with some practical and interesting points. During his 25 years at the Manchester Royal Eye Hospital nearly 213,000 cases of accident had been treated, and 1448 of those had been in-patients under his care. There were among them 859 cases of penetration or rupture of the globe. The fullest possible history of cases of penetrating wounds should be obtained, and it must be determined whether complete penetration has taken place, and whether the mechanical agent has been withdrawn or still remains in the eye. When examination by ordinary methods failed, perforation could often be proved by means of the slit-lamp.

First as to the *cornea*. If the wound in it was small and aseptic, he said, no active surgical treatment was required. If the iris was prolapsed or caught in the deeper part of the wound, a foreign body was not likely to be still retained. If there was no such prolapse there was a greater probability that the foreign substance was still in the eyeball. For prolapsed iris the operator could do either (1) reposition through the wound (often unsuccessful); (2) reposition by making a small corneal incision with a keratome at a point 180° from the wound, and passing in an iris repositor or blunt hook, and separating the iris from the cornea by traction; or (3) excision of the prolapsed portion, which is the usual method he had followed. If the decision reached was to excise the prolapse, he advocated, in suitable cases, the use of small, fine-ribbed capsule forceps, especially when the iris had become friable owing to inflammatory changes a few days after the accident. When the corneal wound was large and tended to gape he favoured suturing the cornea, using Webster Fox's slit-ring forceps. Horse-hair or the finest silk-worm gut were the suture materials he recommended. In some cases it was an advantage to raise the conjunctiva at the corneal limbus, undermine it for some distance, and so suture it that the wound was well covered. For ragged and irregular wounds a conjunctival covering was desirable, and for this he suggested the Nuel suture. He discussed the disadvantages of suturing the conjunctiva over the wound. When there has been a delay of several days before the ophthalmic surgeon is consulted Mr. Clegg said that immediate operation was sometimes needed, but each case must be decided on its merits. Where iris was prolapsed or adherent to the corneal scar, and in two or three weeks the eye was quiet, in most cases operative interference should be undertaken to relieve dragging. This could be done by one of three methods: (*a*) An iridectomy at a position diametrically opposite the site of the wound; (*b*) an iridectomy at either side of the anterior synechia; (*c*) complete severance of the attached portion from the rest of the iris, with or without partial iridectomy.

Mr. Clegg next discussed the question how far it was safe to leave a traumatically produced anterior synechia in a quiet eye months after an accident. Mere perforations or clean cuts were left to recover as best they could. Wounds of the lens, associated with penetration of the globe, always complicated matters if there was anything more than a fine tear in the capsule not large enough to allow aqueous to invade the substance. With regard to the question as to whether it was advisable to remove lens substance when there was a recent wound of the cornea, he thought extraction (when there was a hard nucleus), or expression through the original wound, or lavage, or suction of the soft cortex should be done when there was extensive rupture of the capsule, as the presence of lens substance in the anterior chamber increased the possibility of sepsis, diminished the osmosis at the filtration angle, and might even lead to endophthalmitis phakoanaphylactica. But when the corneal wound was not large and the lens substance not greatly swollen, the removal of the lens could be left to absorption in a young subject, or to a later extraction in a person over 30 years of age. If vitreous protruded into the anterior chamber little could be actively done except when it prolapsed through the corneal wound. The prolapse should be snipped off and the eye protected against infection.

When the wound was at the corneo-scleral junction or in the sclera the case was more serious, but there was no longer fear of the "danger zone." If ciliary body or choroid were prolapsed it could only be excised. Even large clean wounds of the sclera might heal well and a useful eye be retained. Covering with conjunctiva was desirable in all cases, and the edges of the sclera could be brought into contact by Nuel's suture; it was rarely necessary to pass the suture material through the whole thickness of the scleral tissues. One late effect of even the cleanest wounds of the sclera might be detachment of the retina, and the question was, Could anything be done to prevent this? If wounds of the sclera were of some days' or even weeks' standing, questions arose other than those connected with the wound itself. In all extensive perforating wounds of the globe it was necessary to consider whether recovery was possible with the retention of a globe which would have useful sight and would yet not be a threat to the fellow eye. It was, he thought, rarely wise to condemn an eye to evisceration or excision as soon as it was seen to have suffered. At least a week should be allowed to pass before condemnation was pronounced, and there was practically no fear of sympathetic trouble during that short time. He asked the opinions of members as to whether any good resulted if an exciting eye was removed when sympathetic disease had already started in the other eye.

With regard to foreign bodies penetrating and remaining on the globe, these were divisible into magnetic and non-magnetic, and both could be classified into radio-opaque and radio-transparent. The first named could be accurately localised by the methods of Mackenzie Davidson or Sweet. Sometimes the foreign body could be seen on focal illumination by the ophthalmoscope, or it was evident on trans-illumination. If a non-magnetic substance, such as glass, was causing no obvious irritation it could sometimes be safely left. Chemically irritating substances, such as copper, eventually led to loss of the globe, hence every possible effort at removal of such materials must be made. Magnetic substances were best removed by the magnet, for siderosis and opacity of lens might otherwise ensue. If the iron or steel fragment were in the anterior chamber, or even in the iris tissue or in a wounded lens, it could usually be extracted through the original wound, though sometimes this wound had to be enlarged. If the fragment was embedded in the iris tissue it was, he considered, good surgery to make the incision over its position and cut off the damaged iris with the imprisoned chipping.

Dealing with other aspects of the subject Mr. Clegg said that excision of a suppurating lacrymal sac was important.

Mr. G. H. POOLEY (Sheffield) said that as a result of many years of experience and consideration he had arrived at the conclusion that the ophthalmic surgeon was justified in applying conservative modern measures to the eye when that organ had received a penetrating wound, and that this policy should replace the more anxious one which in the past had led to many eyes having been excised within a few days of the accident happening to them. Even mild sepsis of the eye could be successfully dealt with, and a blind quiet eye was a better possession than an artificial eye. He divided penetrating wounds of cornea or sclera or both as follows: (1) Without prolapse of iris or other tissue and without the retention of a foreign body or injury to the lens. (2) With prolapse of iris or other tissue but without retention of a foreign body or a lens injury. (3) With or without prolapse of iris or other tissue or injury to the lens, but with the retention of a foreign body within the eye. (4) The last named and injury to the lens in addition. These he discussed in some detail, making the following points. A straight clean cut of less than 4 mm. in length seldom gaped much, whether it was in cornea or sclera. A wound longer than this should be closed; if in the sclera by the finest 30-day catgut, the sutures picking up the outer layers of the sclera about 1 to 2 mm. from the wound on each side, and so tied as to invaginate the cut edges of the sclera and hold them fairly tightly in apposition. To the conjunctiva should be applied buried catgut sutures. He used a slightly curved needle about 10 mm. long. A gaping corneal wound could be kept in place by indirect suture. In the cases in which a part of the iris was prolapsed, the portion should be picked up, gently pulled a little further out of the wound, and cut off. Prolapsed portions of ciliary body, choroid or retina, and beads of vitreous should be cut away. Foreign bodies should be removed by the nearest and easiest route. Even if such foreign bodies should be septic, they could be retained for a long time without causing trouble, though they should be removed as soon as their exact site had been determined. He had successfully removed glass and steel fragments from eyes in which they had been reposing for years. Dealing with injuries to the lens, Mr. Pooley advocated well washing the eye out and removing as much of the injured lens as possible, to prevent it from swelling and adhering to the wound afterwards. His rule was to try to save every eye, however badly damaged, deferring his decision as to enucleation until about the third week. If vision was never likely in an eye, and it was the seat of keratitis punctata, he removed it. The question of sympathetic ophthalmia Mr. Pooley discussed in some detail, remarking that no eye should be taken out within the first fortnight; he also entered into a description of the technique of scleral suture.

Mr. CHARLES GOULDEN spoke of the treatment of certain difficult cases of prolapse of iris, and of non-magnetic foreign bodies present in the anterior chamber. The method was to make a small incision opposite the perforating injury, 3 mm. in width, so as to admit a repositor. Then the prolapsed iris was dealt with. If any portion of iris remained entangled in the wound, the repositor could be passed through the eye so as to disengage it. With regard to the treatment of large perforating wounds, especially those which perforated the sclera, he thought, contrary to Mr. Pooley's view, that it was unnecessary and dangerous to insert scleral sutures, because of the likelihood of loss of vitreous. When a serious injury was followed by a gaping wound, a good plan was to make an incision round the conjunctiva, then draw the conjunctiva over the wound, and so close it. He discussed the technique of removing magnetic foreign bodies by means of the electro-magnet.

Mr. M. H. Whiting pointed out the advantages of the Haab magnet over the Mellinger for the extraction of magnetic substances from the eye. The horse-collar of the latter instrument, its smaller power compared with that of the Haab, as well as the difficulty of preventing it touching the eye when being used, were among the factors mentioned.

Mr. Elmore Brewerton said his practice when he encountered prolapse of iris was to make an incision less than 90° from the wound before dealing with the prolapsed iris.

Mr. T. Harrison Butler said he had been using the Mellinger magnet for 15 years and had not seen the disadvantages from it which Mr. Whiting mentioned. With regard to sympathetic ophthalmitis, he considered that by removing the exciting eye in the early days many eyes would be saved. But it was necessary to keep careful watch with the slit-lamp. If the latter showed commencing danger he at once instituted the treatment as for actual ophthalmia. This had resulted in the saving of several eyes.

The President said that while it was true that an eye could safely be retained a fortnight or so without risk of sympathetic ophthalmia, he recently had a case in which that complication ensued ten days after an apparently trivial injury, accompanied by keratitis punctata, so that the eye had to be excised.

Mr. Clegg and Mr. Pooley replied.

Clinical Cases.

Mr. J. D. M. Cardell showed and carefully described a case of Kruckenberg's spindles in a single woman aged 30. By means of the slit-lamp Miss Ida Mann found that the pigment was in the posterior layers of the cornea; it seemed to consist of a multitude of closely-set brown rings. Thomson and Ballantyne regarded the condition as congenital.

Mr. Pooley showed two cases of punctured wound of the cornea, in association with his remarks in the discussion of that subject.

Reviews and Notices of Books.

HANDBOOK OF DISEASES OF THE THROAT, NOSE, AND EAR.

Edited by A. Denker (Halle) and O. Kahler (Freiburg). Vol. I., Diseases of the Air-passages and Mouth: Anatomy, Development, Physiology, Methods of Examination. Berlin: Julius Springer; Munich: J. F. Bergmann. 1925. Pp. 1068. M.84.

This volume is the first of a great work which, when complete, is to consist of nine volumes. Of these the first five will deal with the upper air-passages, the next three with the ear, and the last with the thyroid and thymus glands and external structures of the neck. No fewer than 120 authors are concerned in this work, of whom 21 contribute to the present volume. This, consisting as it does largely of the spade-work preliminary to the actual description of diseases and their treatment, is perhaps less intrinsically interesting to the practising laryngologist, but it presents an extremely thorough foundation for what is to follow. Even the comparative anatomy of the nares, fauces, and larynx, as well as their embryology, is described and illustrated, that of the nares being particularly good. In the section on physiology the physical characteristics of odorous substances, and the conditions which influence their absorption, are well explained by Prof. Zwaardemaker, of Utrecht, who, indeed, covers the whole subject of olfaction, of which he has made a special study. Similarly, Prof. Skramlik, of Freiburg, deals at length with the sense of taste. The chapters on methods of examination are likewise full of detail, but here a certain narrowness of outlook becomes apparent. Under anterior rhinoscopy only one speculum, Hartmann's, is advised and illustrated; of bronchoscopic methods, distal illumination is dismissed in five lines as unsatisfactory, and Chevalier Jackson is not mentioned, except in the list of references at the end of the chapter. Indeed, the workers of other countries receive throughout scant recognition. The book is provided with a good index, a detailed table of contents, and a long list of references at the end of each chapter. There are 709 illustrations, all good, and some of them, notably the photomicrographs, are beautiful examples of colour printing. As a work of reference this volume will be of great value to specialists.

THE MIND IN HEALTH AND DISEASE.

An Introduction to the Mind in Health and Disease. For Students and General Practitioners interested in Mental Work. By T. Waddelow Smith, F.R.C.S., Deputy Medical Superintendent of the City Mental Hospital, Nottingham. London: Baillière, Tindall and Cox. 1925. Pp. 235. 10*s.* 6*d.*

In setting out to write an introduction of this kind Dr. Waddelow Smith has undertaken a difficult task. Such a book must of necessity be elementary, but even so, the author surely underrates the equipment of his readers, who are presumed to be medical men and students, in a passage such as the following, from the anatomical description of the central nervous system:—

> "The membranes . . . are continued all over the cerebral hemispheres and have between them and the nerve cells of the hemispheres a layer of cerebro-spinal fluid, so we find the little nerve cells, all over the surface of the brain and also at its base and in its substance, are bathed by this nourishing fluid by means of the layer just described and the ventricles."

In the section dealing with mental disorders the author has a considerable experience of mental work behind him, and there are many practical hints which should be valuable to the beginner. But here the purely Freudian definition and interpretation of the morbid phenomena is to be deplored. It is hardly a generally accepted view, for example, that the anxiety neurosis is "characterised by the failure of the individual properly to adjust his or her somatic and psychic sexuality." In an introduction to what will be of practical utility it is very important that the reader should be guided aright, and we do not feel that this book can be wholly recommended as a help in difficulties.

Old and New Viewpoints in Psychology. By Knight Dunlap, Professor of Experimental Psychology in the Johns Hopkins University. London: Henry Kimpton. 1925. Pp. 166. 10*s.* 6*d.*

There is a growing number of practitioners and laymen to whom psychology is an extremely interesting side-line. It may require a great deal of patience, as well as previous knowledge, to read appreciatively an exhaustive text-book, and many readers are content to derive their knowledge from small synopses of more or less doubtful authority. Prof. Knight Dunlap's book is a very good example of this "popular" class of work on psychology, while it carries exceptional weight, for the author is well known as a conscientious teacher. The five articles were originally delivered as lectures; those on mental measurements and present-day schools of psychology are dull, but give an impartial survey of recent progress in both these subjects. The psychology of the comic is a good piece of constructive reasoning on a subject of universal appeal, and the article on spiritualism is less speculative and carries a sober warning with it. The last, on the reading of character from external signs, is frankly negative. On the whole, the book shows the defects of any random collection of articles or lectures. It lacks vitality and coherence, besides which the writer is too dogmatic for such a controversial subject.

THE EMOTIONS.

Experimental Investigations into the Emotional Life of the Child Compared with that of the Adult. By HELGA ENG, Oslo. Translated by GEORGE H. MORRISON, M.B. Edin. London: Humphrey Milford, Oxford University Press. 1925. Pp. 243. 21*s.*

A LARGE amount of work has already been done in measuring the physical concomitants of emotion, and in the book before us Miss Eng sets out to answer the question whether psychical experiences of a definite character are accompanied by definite changes in the volume-pulse curve and in the respiratory curve, and, secondly, whether such changes in children might indicate a feature peculiar to the child's emotional life. Using the kymograph, the pneumograph, and the plethysmograph, the author finds that the emotions dealt with in the experiments can be arranged in three pairs, each pair showing opposite expression changes on the recording instruments; attention and activity, displeasure and pleasure, depression and excitement are thus opposed, the first mentioned in each pair being marked by a fall in the volume curve, decrease in pulse height, retarded pulse, and retarded respiration, whilst the second shows opposite changes. In experiments on the effect of stimuli no difference was found between children and adults, but a phenomenon, which at first sight might be expected to vitiate the experiments, proved to be of interest. The spontaneous emotional state of the subject, as revealed by introspection, often found expression in the curves, and it is here that age differences became manifest, for spontaneous emotions were, in the case of children, mostly related to sensory impressions, whilst in adults they were more often connected with events of greater personal psychical content; moreover, in these spontaneous emotions, pleasure is more notable in the child and displeasure in the adult. The author concludes with an expression of the opinion that the physiological processes concerned are "definitely dependent on the psychical processes, and not the other way round." About half the book is taken up by tabular records of experiments, and nine plates are devoted to reproductions of actual tracings. To describe laboratory investigations of physiological reactions as an investigation of the emotional life of the child may disappoint those readers who regard that emotional life as made up largely of personal problems and the inter-play of instinctive tendencies. But to say so is in no way to belittle the value of this record of conscientious work. The translator has done his part well, and the book will interest all who are concerned with youthful behaviour.

PHYSICAL SIGNS.

Perkussion und Auskultation. By Dr. HERMANN VIERORDT, Professor of Medicine at the University of Tübingen. Berlin and Vienna: Urban and Schwarzenberg. Pp. 95. M.2.

THE author of this little book has succeeded in condensing his information so well that practically all the student may require to know about percussion and auscultation (as far as they can be acquired from a book) is to be found in these 95 pages. Other parts of the body besides the chest are dealt with as far as their examination by percussion and auscultation is concerned, and the reader is taught how to distinguish between ascites and an ovarian cyst, and how to percuss such organs as the kidneys when they are displaced from their normal site. A book like this is useful to the busy practitioner who, without it, is apt to fall into slipshod ways and to simplify his technique to the vanishing-point. Under such circumstances a small book, which will slip into an overcoat pocket, may jog its wearer's memory, reminding him of those diagnostic methods from the practice of which, owing to pressure of time and want of contact with his fellow practitioners, he has lapsed.

TUBERCULOSIS.

Diagnostik und Therapie der Knochen- und Gelenktuberkulose. Second edition. By Dr. EUGEN KISCH. Leipzig: F. C. W. Vogel. 1925. With 6 tables and 367 illustrations and charts. Pp. 296. M.20; bound, M.23.

THIS profusely illustrated work comes from the Hohenlychen Institute for Surgical Tuberculosis, attached to the University Surgical Hospital of Berlin under the direction of Prof. A. Bier. Hohenlychen may be said to be to Germany what Alton is to England; and, like its English counterpart, Hohenlychen is a standing demonstration of the fact that heliotherapy is not a monopoly of the Alpine and sub-Alpine levels. It is an institution where a great variety of therapeutic measures serve the patients' needs. Hohenlychen makes considerable use of treatment by passive congestion, and those who have abandoned this form of treatment in surgical tuberculosis may wonder if the success of hyperæmia at Hohenlychen may not be due to the many other remedies provided there. The guiding principles of Hohenlychen are that surgical tuberculosis is a disease for conservative treatment, that success can be achieved at any altitude, and that only in exceptional cases should the surgeon resort to the knife. The book is divided into two parts, general and special. The former deals with the physiology of pigmentation, the experimental foundation of the combined treatment with sunlight and hyperæmia, the actions of various forms of artificial light, and the technique of their administration. Information is given as to the action of iodine taken by the mouth in association with passive hyperæmia, and as to the improvement to be effected in the general condition of debilitated patients by the intravenous injection of the blood of mammals other than man. In the special part, an account is given of the disease as it affects each structure, and a whole chapter is devoted to a study of the re-absorption of tuberculous sequestra. The book is a valuable summary of modern German teaching.

Contributions to the Study of Tuberculosis by the Research Department, National Jewish Hospital for Consumptives. Denver, Colorado. 1924.

THIS large volume, which is the fifth of the series, is a collection of the papers published by authors associated with the Research Department of the National Jewish Hospital for Consumptives. The earlier papers deal with the problems of tuberculosis in a more or less general manner. Several papers on research follow, and the last seven contributions are clinical. Most of the papers published in this volume have already appeared in some American or English journal, but the volume will serve the useful purpose of showing the patrons of the hospital the very considerable output of the Research Department.

Recovery Record for Use in Tuberculosis. Second edition. By GERALD B. WEBB, M.D., and CHARLES T. RYDER, M.D. New York: Paul B. Hoeber, Inc. 1925. Pp. 79. $2.

THE first half of this book contains hints on how to recover from tuberculosis, and the second half contains charts on which the patient is invited to record his temperature, pulse, weight, general notes, and questions for his physician. On each page, above and below the chart, there is a proverb intended to give the reader a hint as to how to think and live. Both the advice given in the first half of this book and the proverbs quoted in the second half show that the authors attach more importance to rest than to any other factor in recovery from tuberculosis. To the advocates of exercise as a method for treating tuberculosis is addressed the following quotation from Trudeau: "I know I have hurt nobody by rest, but I am quite sure I often have by allowing them to exercise." Solly is quoted as having said: "The wise have four times as good a chance to recover as the foolish." This is surely an over-estimate of the fool's chance.

Tuberculosis: Its Prevention and Treatment. By J. Laird, L.R.C.S. & P.I. Second edition. Bristol: John Wright and Sons, Ltd. 1925. Pp. 130. 5*s.* 6*d.*

The chief feature of this little book is its advocacy of calcium in the prevention and cure of tuberculosis. Calcium, it would seem, is the key to the problem, not only of tuberculosis, but also of such diseases as cancer. In the first instance its influence is beneficial, in the second it is detrimental, for "cancer is chiefly a disease of advanced life, when the salts of calcium are in excess in the system, and may act as the predisposing cause of the disease." Medical readers may doubt whether the solution to complex problems can be so simple as the author thinks.

Veterinary Diagnosis and Treatment.

By G. E. Jorgenson, A.B., M.D., N.D.V., former State Veterinarian of Iowa; Consulting Pathologist and Associate Editor, *North American Veterinarian.* London and New York: D. Appleton and Co. 1925. Pp. 441. 12*s.* 6*d.*

The author is evidently well informed and always gives a reason for the conclusions he forms and the treatment he adopts. This somewhat uncommon practice should appeal to readers who wish to be rational. He gives 132 case reports of wide range; his treatments seem to have brought about a high proportion of recoveries. Case 8 (fibrinous pneumonia in a horse) and Case 10 (pneumonia in a cow) seem to have been treated, contrary to orthodox practice, by purgatives. However useful in bronchitis they should be given cautiously in serious pneumonia. It is somewhat surprising to learn that the author has never heard of epilepsy in swine; convulsions, falling, and foaming at the mouth are common, and although they may not be signs of true epilepsy they are certainly epileptical. We do not agree that the diagnosis of cæcal impaction is easy, and the action of drugs is modified by the fact that the cæcum is a cul-de-sac undisturbed by the flow in the main tube. Impaction of the colon often follows impaction of the cæcum. It is impossible to commend the autopsy of the cow with anthrax (p. 282 et seq.), for which the two cases that developed later may well have been responsible.

There is much sound reasoning in this book, and it is well produced. We prefer the author's description of its objects to the publisher's statement that it is "a standard practical guide for all farmers." Farmers would remain uninterested in the sino-auricular node of Keith and Flack, polynuclear neutrophiles, and basophiles.

JOURNALS.

Quarterly Journal of Experimental Physiology. Vol. XV., No. 2.—Corpus Luteum Extracts and Ovulation in the Rabbit, by Walter P. Kennedy. It is now a generally accepted theory that at least one of the functions of the corpus luteum is the prevention of ovulation so as to maintain the rhythm of the œstrous cycle and to avoid superfœtation in pregnancy. There is a considerable amount of clinical evidence that extracts of corpus luteum exert a specific action on the functional activity of the ovary. Extracts were made from a powdered desiccated product and shaken up with the required amount of saline, or fresh extracts were made from corpora lutea dissected out from fresh cow ovaries. The injections were given in the marginal vein of the ear or in one of its larger branches. The general picture of the histological findings was one of degeneration and inhibition of the cyclical changes. The general results are that a substance or substances can be extracted in the cold from the corpus luteum of the cow in the fresh or desiccated state, which inhibits ovulation in the rabbit if injected intravenously in sufficient dosage.—The Significance of the Elastic Tissue in the Human Fœtus, by Evelyn E. Hewer. The wide distribution and early appearance of tissue with a great affinity for elastin stains indicates that this type of tissue plays an important part in the functional development of many organs; its appearance is in certain cases correlated with the time at which functioning of the organ begins.—The Action of Pituitary Extract on Urinary Secretion, by Nicholas S. Craig. Ox pituitary (posterior lobe) was used. The author found that in anæsthetised animals, intravenous administration of the extract produced a definite diuresis. Continuous intravenous administration of pituitary extract in 0·9 per cent. saline solution produces the same result. In unæsthetised dogs pituitary extract administered subcutaneously controls the diuresis which normally would result from the administration of water or normal saline by the mouth. If concentrated saline solution is used diuresis results. The author also deals with the action of pituitary on the absorption of fluid from the alimentary canal and on the blood composition. There are further studies on the pituitary by Launcelot T. Hogben on the "Avine Depressor Response," who finds that the substance present in pituitary extracts causing a powerful depressor response in the bird is a specific property of the fresh gland substance; it does not belong to the category of capillary poisons common to extracts of many tissues, and has no connexion with the histamine-like substance responsible for the secondary fall in carnivora, and seems pre-eminently associated with the pars nervosa; it is present in the pituitary of fishes, amphibia, reptiles, birds, and mammals. Another paper by the same author and Gavin R. De Beer deals with Localisation and Phyletic Distribution of Active Materials in the Pituitary.—The Reactions of the Pupil in the Chloralosed Animal, by R. J. S. M'Dowall. The author observed that if an animal such as a cat be anæsthetised with chloralose the pupil remains of normal size, but is extremely sensitive and rapid in its reactions. The reactions of the pupil give not only an indication of the state of the autonomic nervous system of the animal, but they may be utilised as an index of sensation, not only from areas supplied by the spinal nerves, but also from those supplied by the autonomic nervous system, and as a means of tracing out the paths of afferent impulses in the sympathetic nervous system.—R. J. S. M'Dowall and B. L. Worsnop describe new methods of demonstrating changes in the tone of the arterioles.—W. G. Millar records observations on the hæmatocrite method of measuring the volume of erythrocytes, showing that the speed of centrifuging has an important bearing on the accuracy of measuring the volume of erythrocytes by the hæmatocrite.—A. D. Macdonald, in describing the action of pituitary extracts on intestinal muscle, throws doubt on the commonly held view that the pituitary gland contains a general stimulant of plain muscle-fibres.

Somerset's Mental Defectives.—Sandhill Park, Bishop's Lydeard, formerly the seat of Sir W. P. Lethbridge, was last week opened as a home for the mental defectives of the county of Somerset. The house, built in 1720 by Sir Thomas Lethbridge, and about 150 acres were bought for £16,000, and the building has been adapted by Sir George Oatley, the architect of the new extensions of Bristol University. There is at present accommodation for 119 patients, but the estate is ultimately to be developed into a farm colony for the feeble-minded.

IMPERIAL SOCIAL HYGIENE CONGRESS,

WEMBLEY, OCT. 5TH–7TH.

(Concluded from p. 778.)

ON the afternoon of Tuesday, Oct. 6th, the conference discussed

Social Hygiene in Relation to the Mercantile Marine.

In the absence of Sir George Buchanan, Dr. F. J. Coutts, of the Ministry of Health, introduced a paper prepared by them, in which they mentioned the difficulties met with in trying to treat seamen who moved from place to place. The problem was especially important in view of the part played by certain seaport towns in spreading venereal diseases. International agreement was clearly desirable, but there had been many obstacles, including the system by which in some countries seamen or shipowners were expected to bear the cost of treatment; the difficulty of making a man's case papers intelligible to the medical staff at foreign ports; and the practical difficulty of how to express the results of Wassermann tests. The inquiry into this last had led to the recent researches at Copenhagen into the comparative value of different blood tests for syphilis. The agreement on the international treatment of venereal disease had been signed by Argentina, Belgium, Cuba, Denmark, Finland, France, Great Britain, Greece, Italy, Monaco, New Zealand, Peru, Roumania, and Sweden. The United States was not prepared to adhere to the agreement, but in practice it was hoped that satisfactory arrangements would be made. It was greatly to the credit of the British Social Hygiene Council that the agreement was a practical instrument rather than a mere sign of theoretical unity of purpose. Medical facilities were to be provided free for seamen in the chief ports of the contracting parties; specialist officers were to be available in the clinics, and a card which could be universally understood was to be used. Experience had shown the scheme to be useful and exemplary arrangements had been made at Liverpool. Seamen going abroad were to be furnished with a list of treatment centres elsewhere.

A paper was read for Mr. M. R. K. Burge describing the work of the Joint Maritime Commission set up by the International Labour Office in coöperating with other national and international bodies in the campaign against venereal disease among seamen. Although pleased with the steps taken by Governments to provide treatment, the Commission hoped that such activities would not obscure the necessity for preventive measures. A report on prophylaxis was, he said, being got ready by the International Labour Office.

Welfare Work for Merchant Seamen.

Fleet-Surgeon W. E. Home said in his paper that the valuable services of seamen to the community entitled them to more care. Their occupation, which early removed them from home and its training, was quite exceptional amongst trades, and so were their risks and discomforts. The last official statistics, dealing with the years 1900–02, showed that seamen had nearly twice as many deaths per 1000 as "all occupied males" in England and Wales, and four times as many deaths from accidents. The accident death-rate was double that of coal-miners. Most workmen lived in communities with other people, their health being watched by sanitary authorities; but the merchant seamen had no one specially to look after them and report on their conditions. The United States saw that its men were vaccinated, inoculated against typhoid, or given quinine; but in spite of heavy mortality nothing of the kind was done in England. Accidents and their prevention seemed unconsidered. The problem of venereal disease amongst seamen was the result of a vicious circle. The want of home influence led to drink and mischief; they led to infection, and infection might prevent the man ever having a home of his own. In 1924 the Seamen's Hospital at Liverpool had handled 438 new cases, of which 169 were syphilitic. After referring with admiration to the work of the late Miss Agnes Weston, he said that everything preventing aimless idleness—gymnasiums, entertainments, concerts—must be encouraged, and the Social Hygiene Council was arranging for sports grounds near harbours.

[An analysis by Fleet-Surgeon W. E. Home of the causes of death amongst merchant seamen appeared in THE LANCET of Oct. 3rd, 1925.]

Arrangements in the Empire.

Dr. C. L. Park's paper gave an account of arrangements in Australia by which every seaman reported as infected was taken in charge by the quarantine authorities during the whole time his ship stayed in Australian waters. Hospital beds and specialist treatment were provided for him, and on his removal to another port the treatment was continued there. The Australian laws ensured that infected seamen were kept under observation until their disease had ceased to be infective; but the facilities did nothing towards preventing fresh infection being incurred by the healthy, though recreation was available in certain ports.

Major H. B. Jeffs contributed the information that Canada imposed a fine of $200 for any emigrant brought to a Canadian port of entry suffering from a venereal disease, any such emigrant being deported at the steamship company's expense. Persons rejected for venereal disease might not apply again for entry. He described the free clinics for seamen at Canadian ports, stating that there were 56 free venereal clinics in operation in the Dominion, besides other institutions; about 330,000 treatments were given in a year. Prisoners entering reformatories and gaols were subjected to a Wassermann test and treated if necessary.

Sir Claude Hill assured the Congress that the Red Cross would give all possible help in propaganda. Dame R. Crowdy thought that the Congress had concentrated too much on the technical side of prevention and not enough on the moral factors.

White Slave Traffic.

Mr. S. Cohen read a paper on the suppression of the white slave traffic. He said that it had gradually been reduced to very small proportions because the steamship companies refused to carry the women and the Home Office refused to let them land in England. He hoped that tolerated houses would be put down everywhere; if this were done there would then be no traffic. It was a great advance that Hungary and France had refused to allow any foreign women into their tolerated houses, and perhaps the other Latin countries would follow this lead.

Mrs. Neville Rolfe appealed to Mr. Bascom Johnson (Director of Special Inquiries for the League of Nations) to say whether venereal disease had any special relation to licensed houses. Mr. Johnson replied that they prevailed in the same areas, but investigation of relationship was still incomplete. Prostitutes were in the habit of following the American fleet to Panama for its winter manœuvres; if there were no brothels in which they could find lodging they would not go.

Dr. David Lees complained that a British seaman kept in hospital at a place like Port Said would lose his ship and his pay; and as there was no British Consul there he would be worse off than a foreign sailor in a British port. There should be Government subsidy to set up sailors' homes in every port. The State, through the local authorities, should provide 75 per cent. of funds. He mentioned that Edinburgh was to be invited to build such a home.

Surgeon-Commander T. B. Shaw attributed most venereal disease to drink, and Mr. E. B. Turner, in supporting the plea for sailors' homes, recalled old London conditions.

After the meeting a film dealing with venereal disease was exhibited.

Treatment of Venereal Disease in England.

At the morning session on Wednesday, Oct. 7th, Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, who presided in the absence of Mr. Neville Chamberlain, said that the Government had not been ungenerous in meeting 75 per cent. of cost involved in treating venereal diseases. There were to-day 193 treatment centres in England and Wales, and there were 14 hospitals approved for the accommodation of women and girls and seven special institutions for infected pregnant women. There was much evidence of the increasing willingness of people to come forward for diagnosis. Since the inception of the present scheme in 1917 more than 600,000 persons had attended the treatment centres, of whom about 120,000 were found to be suffering from venereal disease. Since 1920 there had been a steady decline in the total numbers of new cases of infection dealt with at the centres. In 1924 there were only 22,010 new cases of syphilis as compared with 42,805 in 1920, and 31,272 cases of gonorrhœa, compared with 40,280 in 1920. The number of attendances at the clinics during 1924, however, reached a total of about 1,650,000, the highest on record, which meant that the average number of attendances per case had increased and that the importance of persevering in treatment was increasingly recognised. The percentage of cases which ceased attendance at the clinics before their course of treatment was complete had fallen from 47 in 1921 to 39 in 1924. There seemed to have been a definite diminution in syphilis and gonorrhœa during the past five years. The expenditure of local authorities on schemes for diagnosis and treatment had fallen from £450,000 in 1921–22 to £388,000 in 1923–24, and a further drop was expected this year. The saving was due to improved arrangements at the centres and more economical working. Turning to the subject of notification, Sir Kingsley Wood said that so far as experience had been obtained it had not shown that its advantages would outweigh its disadvantages. One city, Bradford, had an Act which required the notification of certain classes of cases, but did not empower the local authority to take any action on receipt of the information. In Canada and Australia legislation was in force setting up conditional notification. In wishing the conference Godspeed he said that one of the tragedies of the present situation in this country was that in 1924 over 5000 persons under 17 years of age had to be dealt with for the first time.

Colonel L. W. Harrison, of the Ministry of Health, said that the report of the Royal Commission in 1916 had stated that the number of syphilitics could not be less than 10 per cent. of the population in the large cities, and his own investigations had led him to suppose that the incidence of gonococcal infection was about three times that of syphilitic. It was estimated that the annual number of venereal disease infections before 1916 was not less than 200,000, but since then there had been provision of efficient treatment and of education. He believed that a very high proportion of cases of syphilis reported themselves, but not so high a proportion of cases of gonorrhœa. In England, as in all other countries where there were good facilities for treatment available, there appeared to be a very remarkable reduction in the incidence of syphilis; but he did not think that any very great reduction in gonorrhœa could yet be expected. The treatment was harder, and to stop the infectivity of the patient was harder; the fight against this disease would be long and difficult. The cost of the present schemes of treatment was about 2½*d.* per head of the population per annum, and a minimal estimate of the ultimate saving showed how economical this was for the nation. A manufacturing concern in Virginia had installed a free venereal clinic for its employees at a cost of $6000 for the first year and had later reported that labour efficiency had increased by one-third, which gave a return of $40,000 yearly for the investment. After pointing out the advantages of clinics being open all day, especially for women with gonorrhœa, who are preferably treated daily by a nurse, Colonel Harrison referred to the necessity of preventing ophthalmia neonatorum and congenital syphilis by taking forethought. He wished to awaken all branches of the medical profession to the fact that congenital syphilis was a horror, and its incidence a reproach. The instruction of medical students gave far too little knowledge of early venereal disease. The curriculum need not be further loaded. Was it not better to spend a few hours learning to treat syphilis in its first stages than to devote many to the pathology, signs, symptoms, and prognosis of the horrible consequences of early neglect?

Progress in the Dominions.

The position throughout the Dominions was then reviewed. Dr. C. L. Park (Australia) pointed out that venereal disease was now being looked upon as a general public health problem. Dr. B. Colquhoun drew attention to the fact that not the least of the evils of the war had been the loosening of social behaviour, and that such institutions as Boy Scouts, Girl Guides, and the Junior Red Cross, and open-air schools for young children, would give a much better chance to the coming generation.

Dr. J. A. Mitchell, Secretary for Public Health for South Africa, said that there was an extraordinary tendency to exaggerate the prevalence of disease amongst natives. In South Africa not more than 2 per cent. of all races had venereal disease, and since inter-tribal wars had been stopped and famines were prevented or checked, the real racial danger was the destruction not of the natives, but of the white population, which might be elbowed out, swamped, or absorbed. In a paper laid before the conference by Lieut.-Colonel Pargett Adams, the incidence and manifestations of venereal disease amongst natives were described. Syphilis was a far less formidable complaint in South African Abantu races than in white or partly coloured people.

In a paper by Dr. Gordon Bates (Canada) it was insisted that the Venereal Disease Acts were of real value from the point of view of the protection of the family. Canada was going forward on the lines of a broad social programme. Mr. John Huxham (Queensland) advocated the interchange of medical certificates between persons wishing to contract marriage. Dr. Draper Bishop (Guernsey) said that as a result of legislation social abuses had been enormously reduced. Dr. David Lees criticised Sir Kingsley Wood as regards economy. If it had been possible to save money let them use the money saved for the attack on gonorrhœa. As regards the problem of large or small centres, he protested against the tendency to establish ad hoc clinics instead of clinics inside the hospitals. A point that was essential was to get a keen medical staff, but it was questionable how long this would be possible under the present rates of payment; he could not advise able young men to go into the work of venereal disease under present rates of pay, and suggested that the Ministry of Health should make part-time appointments, so that the general public, which was not getting as good treatment as hospital patients, could benefit from their experience. Dr. J. H. Sequeira said that the London Hospital had no difficulty in getting expectant mothers into the clinics, because there was no attempt to label the departments as ad hoc departments. Mr. H. Wansey Bayly claimed that self-disinfection, which was in practice in Portsmouth, had resulted in bringing the Portsmouth figures for disinfection considerably below those of Birmingham, a decrease having been seen in Portsmouth, whereas there had been an increase in Birmingham.

Colonies, Protectorates, and Mandated Territories.

The problem of venereal disease in these countries was discussed at the final session of the Congress on Wednesday, Oct. 7th. Papers were submitted by delegates from Barbados, Nigeria, Ceylon, Fiji, Nyasaland, and Palestine.

Dr. A. M. De Silva said that in Ceylon the Government and the public are vigorously attempting to deal with the prevention and cure of venereal disease and that the number of sufferers shows signs of decreasing. In Colombo all houses of ill-fame have been closed; the police strictly enforce regulations against public solicitation; free treatment clinics are available at all the large hospitals, and specially trained doctors travel from village to village. There is no difficulty in getting the people to come for treatment.

Dr. P. T. Harper said that hitherto the inhabitants of Fiji have been immune to syphilis owing to the magical rite of inoculation with yaws practised on children after the eruption of their first teeth. A small percentage of Fijians grow up without having contracted yaws, and the proportion is increasing owing to the influence of the Government and missions. A number of them is also being cured of yaws, and it may be confidently expected that in future syphilis will appear amongst the Fijians and spread. as gonorrhœa is now slowly spreading amongst them. The abolition of indentured labour has lessened venereal disease amongst the Indians. Free treatment is provided at numerous Government institutions for all Fijians, Indians, and necessitous persons, and there are arrangements for treating all infected seamen arriving at the islands.

Nyasaland, Palestine, and Jamaica.

Dr. Meredith Sanderson, describing the conditions in Nyasaland, said that leprosy, plague, trypanosomiasis, bilharziasis, ankylostomiasis, and venereal disease are all endemic. The last can only be dealt with as part of an organised effort to improve the public health as a whole. The problem is political rather than medical; the Pax Britannica is apt to result in boredom, and the adage about Satan and idle hands is very true in Central Africa. Tribes which were moral under tribal rule have become less moral; the marriage tie has been weakened and prostitution is on the increase. Dr. Sanderson considers that tribal discipline may be improved; that the marriage tie should be regularised by civil process; that village schools should give instruction in hygiene; and that a native medical service should gradually be built up.

Dr. J. W. P. Harkness said that syphilis amongst the rural population in Palestine is mild in type and is spread by social rather than sexual intercourse; but its effect on birth-rate and child life is as serious as in Europe. The people are not sexually promiscuous and they marry early; but domestic hygiene is bad. The health department is capable of treating about 2000 patients a year, and instruction in hygiene is given to teachers in Government schools. Education is a very laborious process, and suitable pictorial representations of disease are extremely hard to devise. In 1924 the Supreme Moslem Council consulted the health department as to the practicability of a religious edict forbidding the marriage of Moslems who do not submit medical certificates of freedom from venereal disease, and there is a possibility of this being tried in one district. Gonorrhœa is not unduly prevalent in Palestine, though there are epidemics of gonorrhœal ophthalmia. The administration has never countenanced the system of registration and compulsory examination of prostitutes, and the number of brothels in Jerusalem and at the ports is less than in 1918. Syphilis and gonorrhœa are notifiable but not by any means always notified. The general situation is promising.

The Bishop of Jamaica said that the population of Jamaica was about 9 millions, of whom some 15,000 were Europeans. The percentage of persons suffering from venereal disease has been estimated at its lowest as 40 and at its highest as 80. Until recent years the Government paid very little attention to the problem. In the past six years a committee, of which the Bishop is chairman, has been at work, and it has made representations to the Government, broadcast literature, and instituted courses of lectures. All this has made a considerable stir amongst the people. The Bishop said that adequate sums of money are required to deal with the situation effectively. If there is to be success in the great campaign throughout the Empire it must be by legislators, medical men, and ministers of religion working together.

Mrs. C. Neville Rolfe (secretary-general to the Congress) said that the outstanding need is for assistance to the medical services in the Colonies.

In winding up the conference Colonel Harrison pointed out that expenditure on venereal disease is a paying proposition.

WORKSHOPS FOR THE TUBERCULOUS.

HEALTH WEEK CONFERENCE.

A CONFERENCE in connexion with Health Week was held at Holborn Town Hall on Oct. 7th with the object of making known and popularising workshops for tuberculous patients in the borough. In opening the proceedings the Mayor (Councillor H. W. Coleman) said that Holborn was able to demonstrate the possibility of such workshops by the success of the Spero factory in Hatton Garden.

Dr. C. H. Walmisley, chairman of the Public Health Committee of the London County Council, described the difficulties which faced the local authority which tackled the tuberculosis problem. It was very important that notification should be received early. Sanatorium treatment was often difficult because the financial position of the patient made him anxious, and his benefit under the National Health Insurance was for a limited time. At the sanatoria the patient must attain to six or eight hours' work a day; to do only four or six hours was unsatisfactory because he might then go home and try to do eight, which would lead to relapse. This was where the system of workshops came in. The tuberculous patient who did only six hours' work a day was either paid for half a day's work, in which case his family could not live, or else he was paid for a full day's work, when the goods he produced could not be sold at an economic price. He suggested that surplus funds under the National Insurance Act should be devoted to subsidising workshops. One of the worst possible ways of treating tuberculosis was to take a man away from a sanatorium and let him sink in his way of life. Even able-bodied men had great difficulty in finding work to-day. A workshop, he said, was quite different from a colony, where a family was taken from its surroundings and put down in a new environment. The workshop allowed the man to live at home and go to work under conditions suitable to his disease.

Funds and Subsidies.

Dr. Otto May, of the Prudential Assurance Company, said that early deaths from tuberculosis accounted for a heavy item in claims against insurance funds, and that the company were interested in any way of preventing them. The suggestion that they should bear the whole cost of subsidising workshops had the merit of simplicity, but although they might be induced to help in suitable schemes they had, in fact, very little surplus money. The approved societies, however, had large surplus funds under the Insurance Act, and there was no reason why they should not allocate some of them to the provision of tuberculosis workshops.

Dr. Haden Guest, speaking as a Member of Parliament rather than a doctor, said that he believed that the remedy of the great social problems did not lie with medical science but in an alteration of social conditions. We were preserving in our cities—in London—manufactories of tuberculosis. Prevention was not a question of serums but of hygienic surroundings. The real difficulty in getting early notification was that the workman did not want to go on the sick list and lose his wages. It could never be obtained until there was some means provided of supporting such a man, and this was one of the key-ways of dealing with the situation. At present many cases escaped notification altogether. He would like to see workshops provided in the early stages, so that the men could get better before they got bad, and he agreed that workshops were useful for men who were recovering. Subsidy for this work would be an altogether useful and commendable expenditure which would really bring in dividends. He thought that trade unions might be asked to coöperate as health propagandists, and that they could do useful work. He had himself been a member of the L.C.C. Public Health Committee, and considered that although it was doing valuable work it should do three times as much. The present tuberculosis figures ought to be halved before there was any cause for satisfaction.

Dr. Harry Campbell said that many patients who had active tuberculosis were capable of light work. In workshops they would have medical care, congenial work, and new interests, and could be taught to avoid infecting others.

The Hatton Garden Workshop.

Dr. N. D. Bardswell said that the Spero leather factory was the first work centre of its kind to be established in London, and, so far as he knew, the first in the country. It had been opened in 1922 by the Central Fund for the Industrial Welfare of Tuberculous Persons, and the employment scheme consisted of three units—namely, the central office and showrooms at Denison House, Vauxhall Bridge-road; the specially arranged hygienic factory at Cross-street, Hatton Garden; and the training centre at King George V. Sanatorium, Godalming, whence employees for the factory were recruited. Dr. Bardswell described the conditions at Hatton Garden. The factory makes high-class fancy leather goods, such as purses, bags, and wallets, and sells them in the open market. The full complement of the factory is 23 men. At present there are 22 employees, of whom 11 are ex-Service men; five are married. The minimum rate of wages to trained men is 8½*d.* per hour, or 30*s.* a week, which is the same rate as prevails in the Lord Roberts' workshops. On increased efficiency the rate is raised, and the wages of the trained men at present vary from 44*s.* to 30*s.* 3*d.* The men prefer payment per hour to piecework. Working hours are from 8 A.M. to 5.30 P.M., with one hour's interval for dinner and ten minutes for lunch; on Saturdays the factory closes at mid-day. Two weeks' holiday on full pay is allowed during the year. The workshop and business generally are managed by a committee of five members, one of whom is an employee of the factory nominated by his fellows, and a highly skilled leather worker is responsible for the routine work in the factory. The medical supervision of the employees is exercised by their usual medical attendants, in association with the tuberculosis officers of the various boroughs, whilst their social welfare and that of their dependants is looked after by a small informal committee. Owing to the relatively low wages that can be earned, financial difficulties continually call for attention. On the social side of its work, the Central Fund have found invaluable helpers in the British Red Cross, the Charity Organisation Society, the various borough care committees, and other social service organisations.

Results of the Experiment.

After three years' experience, continued Dr. Bardswell, the following conclusions had been reached. (1) The organisation of employment for tuberculous persons is a practical proposition; but the training of tuberculous persons for a skilled trade is not generally possible. Were the Central Fund to begin over again, they would not choose a skilled trade, such as leather work, but rather some trade demanding the minimum of training in which the output of workers could be assisted by the use of simple machinery. This lesson of the Fund's experience could not be too strongly emphasised. (2) Medically speaking, tuberculous persons working in a city factory under conditions such as can be seen in Hatton Garden do very well. The workers, all definite cases of pulmonary tuberculosis, and many of them serious cases, had maintained their health or improved, and as a means of after-care the success of the factory was fully proved. (3) On the important question of cost it was less easy to be dogmatic. The business was young, though growing, and had a long way to go before it could be considered established. To start a new business at a time of general commercial depression was very difficult; markets were shy and competition relentless. Added to this there was the handicap of employees whose output was lower and slower than that of their competitors. Before anything else, a factory for tuberculous persons needed a certain and constant sale for its products, and this should be the first consideration of the promoters of any scheme of employment. The rent of the premises at Hatton Garden was £150 a year; gas, heating, and cleaning cost £90. The cost of altering and equipping the factory had been £400, and the salary of the workshop manager was £350 per annum. Broadly speaking, the income from sales of goods at present covered the whole amount paid in wages to the employees and the cost of raw materials used in the factory. All other expenses, such as rent, taxes, insurance, wage of manager, office expenses, and assistance to the employees, had to be met from other sources, and these amounted to more than £1000 per annum. As everyone knew, a factory for the partially disabled must be subsidised; but it was surely a wise expenditure which maintained in health and work those who otherwise would be sick and without the means of work.

Agreement and Criticism.

Dr. G. Quin Lennane, medical officer of health for Battersea, welcomed the Holborn work as a pioneering experiment. Dr. H. de C. Woodcock said that the fact that this scheme had proved practically an economic success under present difficult conditions seemed an argument for making workshops for the tuberculous a national question.

Mr. F. Berliner (Finsbury) said that many skilled men were out of work, and in his opinion, by the subsidy of workshops, the wrong men were being put to the work. Those who could not compete commercially in one sphere should have the opportunity to work in another, and the influx of healthy men to the towns should be met by letting the tuberculous, for instance, go out into the country. There were 21 million acres available for afforestation, and there was light work, such as the care of nurseries and putting up netting and fences, which he thought suitable for the tuberculous. At Hatton Garden it had been found that the only way to carry on was to observe ordinary business hours, and even then the lack of speed of the workers was a serious handicap.

Councillor the Rev. H. Ross said that the mental and moral welfare of the men was important, and that they did not want to move from their homes and surroundings. He agreed that as many as possible should go on the land, but more workshops were needed.

Glasgow Post-Graduate Medical Association. The Association has arranged a course of instruction from November till May on similar lines to those of former years: (1) A series of demonstrations will be held each Wednesday afternoon commencing Nov. 4th. The programme includes medicine, surgery, obstetrics, and a number of special subjects. (2) Special courses in ophthalmology have been arranged by the staff of the Glasgow Eye Infirmary. Instruction in other special subjects will be arranged by other hospitals to meet the expressed desire of graduates. (3) A number of clinical assistantships are available in the wards or out-patient departments of various hospitals for periods of three months' tenure. The syllabus may be obtained from the Secretary of the Association, Dr. James Carslaw, 6, Woodside-crescent, Glasgow, C.3.

THE LANCET.

LONDON: SATURDAY, OCTOBER 17, 1925.

PHYSIOLOGY AND ORTHOPÆDICS.

This is the season for introductory and presidential addresses, and there is some risk that in the flood of October oratory the paper read by Mr. Blundell Bankart before the Orthopædic Section of the Royal Society of Medicine on Oct. 6th may attract less notice than is demanded by its merits and the importance of its subject. Every surgeon ought to be familiar with the latest established facts concerning the physiology of muscular action, and in no specialty is such knowledge required more urgently than in that of orthopædic surgery. As Mr. Bankart very truly pointed out, "its ultimate aim is the restoration of function, so that those who profess to deal with disorders of bodily function must have some knowledge of the normal functions of the body." Advances in pure science are apt to remain unapplied in practice for a long time, and especially is this true of the science of physiology, which advances not often by leaps and bounds, but for the most part by many small creeping movements. It is very well then that there should be vigilant observers who bring the latest discoveries of the laboratory to the notice of the clinician. Even if, as in the case of recent experiments into the sympathetic innervation of voluntary muscles, improvement in practice does not necessarily follow, yet the discussions which arise around it ventilate the subject and tend to maintain and improve the liaison between the experimenter and the practitioner. It is some years since Prof. Sherrington published an account of his work on the postural activity of muscle, and showed that although there is only one kind of striated muscle cell, there are two kinds of muscular action, one of which brings about movement, while the other resists or prevents it. This fact is of interest to all clinicians, but it is of special importance to orthopædic surgeons, not only in the treatment of spastic palsy, but in the treatment of errors of posture, which they may hope to correct not by the education of muscles, for they are the mere slaves of nerve-fibres and incapable of learning or being taught, but by educating the nervous mechanism. Whether the faulty posture affect a segment of a limb or the whole trunk and lower limbs, if it is due, as is so often the case, to a lack of tonic muscular action, its correction can only be hoped for as the result of improving the efficiency of the neuro-muscular mechanism which produces postural tone. It therefore follows that resistance exercises should be preferred, which call for the tonic contractions which resist movement and are more likely to produce good results than free voluntary movements.

Probably one reason why the drill sergeant has been so much more successful than the civilian physiotherapist in producing changes of trunk posture, is that he relies more on making the recruit resist tendencies to sag and slouch than on active movements which are supposed, probably erroneously, to improve posture. But as postural tone is concerned in the regulation of all voluntary muscular movements, the performance of these latter must have some, if only a small, effect on the development of the former. All who are concerned with physiology—among whom at least all orthopædic surgeons should be included—were interested in the posthumous publication[1] of two lectures by that brilliant Australian physiologist Dr. J. I. Hunter on the Sympathetic Innervation of Striated Muscle, in which he claimed to have shown as the result of experiment that the postural tone of Sherrington was really composed of two kinds of action which he called plastic tone and contractile tone respectively, and further, that every striated muscle consisted of two kinds of fibres, of which one was innervated by sympathetic nerve-fibres and the other by the ordinary medullated nerves of the cerebrospinal system. Dr. N. B. Royle went further and applied[2] the lessons learned from Hunter's experiments to the surgical treatment of spastic paralysis by sympathetic ramisection. This was less than a year ago when the new discovery was hailed with enthusiasm as a great advance in our knowledge of neuro-muscular physiology, and the operation based upon it was credited with great results. Unfortunately, Dr. Hunter was cut off in his youth and before he had an opportunity of profiting by the criticisms to which his new observations and theories were speedily subjected. Had he lived he would doubtless have profited by them and have been the author of discoveries which would have stood the test of time and conduced to his lasting fame. There used to be a cynical saying to the effect that the average life of a new physiological fact was three years. To judge from the review of the whole subject by F. M. R. Walshe, which appeared in the September number of *Medical Science*, the life of Hunter's new facts is to be measured in months not in years. Dr. Walshe concludes by saying that the analysis of postural tone into two separate components has proved to be artificial, that, in short, postural tone cannot be so split up and that sympathetic motor innervation of striated muscle has not yet been satisfactorily established. As regards the operation of sympathetic ramisection its results have been most disappointing, even in the two cases chosen by Royle out of 25, and operated upon by him in Boston.

To these experiences of the results of sympathetic ramisection which are referred to by Dr. Walshe there may be added those of Mr. Bankart, who stated that he had performed this operation for spastic palsy ten times without any beneficial result. As he is known as a most skilful operator and as one who has paid special attention to the operative treatment of Little's disease, it is not likely that much more will be heard of this method of treatment. Mr. Bankart also referred to the interesting but rather baffling question of muscular atrophy after injuries to bones and joints, which is especially noticeable in the quadriceps after fractures of the patella or of the lower end of the femur, and pointed out that it was the postural tone of the muscle that was most conspicuously lacking, and that while the power of voluntary contraction could be increased by active movement, massage and electric methods, we could only hope to improve the postural tone by proceedings which tend to stretch the muscle; in other words, by resistance exercises. Flexor muscles are not postural, and therefore those who hope that the transplanted hamstrings will be capable of controlling the knee-joint are doomed to disappointment, for the chief function of the quadriceps is not to extend the knee but to prevent it from bending, in which function the postural tone is alone concerned. Several other questions concerned with muscular activity which interest the orthopædic surgeon were lightly touched upon in this address, such as "What is cramp?" and the relations between intestinal stasis due to faulty posture, and arthritis. Mr. BANKART claimed, and we think made good his claim, that of all branches of surgery orthopædic surgery is the most advanced, for it has recognised, as all surgeons should, the importance of reckoning with the progress of physiological knowledge and applying its lessons on treatment. The physiology of muscular movement is but one instance of the fundamental relationship between physiology and orthopædic surgery.

ANOMALOUS APPETITES.

PERVERTED appetites are well known if they are not very common. People and animals eat earth, hair, dung, cinders, curious pickles, and all sorts of things because they want to, and indeed in some cases because they feel they must. Normal appetite is a pretty good indication of normal need as we are now coming to learn, and it will be of much interest to discover the rationale of some of the fantastic cravings which are known. The last number of *Physiological Reviews* (1925, v., 336) contains a good account by Dr. H. H. GREEN of one case of which the explanation is apparently ascertained. Osteophagia in cattle in South Africa was mentioned by the traveller LE VAILLANT as far back as 1785. He noticed that the cattle eagerly searched for the bones left by his dogs and chewed them with relish, and he attributed the habit to the poorness of the grass on which the animals had been fed.

In recent times the habit has been so widely spread that in its milder phases it has come to be looked upon as almost natural. The least degree of craving is shown by a taste for sweet bleached bones alone; greater degrees by a readiness to gnaw at bones in increasing stages of foulness and putrefaction until the stage is reached at which the animal will devour any miscellaneous rubbish that it can get at. With this dirty food it is liable to pick up a toxigenic anaerobic bacillus (*Parabotulinus bovis*) which gives rise to the serious and fatal poisoning known as lamsiekte, and it is mainly the losses due to this which have concentrated attention on the osteophagia which always precedes it and which by itself causes noticeable deterioration of growth, milk-yield, and general condition. THEILER and his co-workers have shown fairly conclusively that osteophagia is caused by a deficiency of phosphorus in the diet. The administration of any phosphorus compound which can be utilised by the animals will cure it within a few weeks —bran, bone-meal, calcium phosphate, sodium phosphate, and phosphoric acid are all effective. It does not, of course, follow, because ague can be cured by bark, that malaria is caused by the absence of quinine, but in the present instance the indication from therapeutics is corroborated by many details of the relation of osteophagia to locality and season. Oxen, too, require the smallest ration of bone-meal to keep the craving under, growing stock perhaps twice as much, and milking cows still more. It seems, then, that osteophagia is a highly intelligent response to phosphorus deficiency, though the animals have not quite enough chemical knowledge to jump at precipitated calcium phosphate towards which cravers show no inclination. The craving in its more exaggerated form will also lead cattle to eat any odd rubbish whether it is rich in phosphorus or not, and in so doing they will often get killed by botulism: *quem vult deus perdere prius dementat.*

These curious facts suggest reflection on two lines. In the first place, as to how far similar "perversions" of appetite may have similar explanations. Are hair-eating and feather-eating expressions of a need for something in keratin, possibly the cystine? N. ZUNTZ found that he could increase the wool of sheep by feeding them with partially hydrolysed keratin, and one of his colleagues who took the preparation had to shave twice a day instead of once. Is coprophagia an attempt to get something which has been made by bacterial action in the bowel?—it has often been noticed in rats fed on vitamin-deficient diets. In the second place, as to how far it is phosphorus that is effective in restricting the quantity of live matter on the world. It is not an abundant element and most of what is in sight is in plants and animals; in the sea, at any rate, there is only just enough to go round—in other words, it becomes a limiting factor. Some wheat lands in America are useless without the addition of phosphate, and as Dr. GREEN points out it seems likely that the "cripples" of stock in New Zealand, Australia, and Texas is also aphosphorosis. Man, at any rate, has found it worth while—and not a little profitable—to go far afield to fetch phosphorus. The deposits in Christmas Island are commemorated in the Irvine Chair of Bacteriology in the University of Edinburgh.

THE VOLUNTARY HOSPITALS OF GREAT BRITAIN.

THERE are in Great Britain 911 voluntary hospitals, with 58,551 available beds, and of these 793 hospitals with 45,091 beds lie outside the metropolitan area, and are the subject of a report[1] to the Joint Red Cross by Dr. F. N. K. Menzies, which is issued this week. There has never been any year, writes Dr. Menzies, in which all the voluntary hospitals paid their way, but, taking the extra-London hospitals as a group, there was a balance to the good for the year 1924 of £453,000 in England and Wales and £696,000 in Scotland, while 61 per cent. of all the hospitals did, in fact, show a surplus of ordinary income over ordinary expenditure. Nor has this favourable balance-sheet been obtained at the cost of diminished activity, for there has been a steady increase in the number both of in-patients and out-patients treated, the total number of new in-patients during the year reaching the figure of 614,069, and that of new out-patients the enormous total of 2,496,485. In their report to the Minister of Health last year the Voluntary Hospitals Commission put the total additional beds required for England and Wales at 10,000, making at a bare cost of £400 per bed a minimum capital expenditure of £4,000,000. Dr. Menzies regards these two figures as an under-estimate of actual requirements and sets himself to answer the question: Can the voluntary hospitals themselves within the next five years provide and maintain without State aid the additional 10,000 beds said to be required? He finds that during the last four years an addition of 4681 beds has actually been made to the voluntary hospitals of England and Wales alone, or an average increase of over 1100 beds per annum, so that the need would be supplied if only the hospitals found themselves able to double the normal rate of increase of their bed accommodation during the next five years. Obviously, as Sir Arthur Stanley points out in his foreword, there are great inequalities in the need, and such a newly populated district as Becontree, where hospital beds cannot be obtained by extension of an already existing institution—for there is nothing to extend—must receive financial help from the State. It will be remembered that the Hospitals Commission definitely asked for a capital grant of £2,000,000 for building purposes, but Dr. Menzies carefully considers the alternative ways in which the necessary funds might be made forthcoming. Closer coöperation between hospitals, so desirable in theory, has proved unattainable in practice, and founders on one of our invincible national traits. Exemption from local rate charges, also unlikely of attainment, can hardly be cogently urged when hospitals, like other ratepayers, benefit so greatly from certain municipal services. On the other hand, exemption from legacy duty would benefit the hospitals to the extent of £150,000 per annum, and make such a difference in the hospital budget that no further suggestion of "going on" the rates or the Exchequer, as Sir Arthur Stanley puts it, would need to be entertained. Dr. Menzies, however, believes himself that the Treasury, given the choice, would prefer a lump sum contribution to such a permanent loss of revenue. The final alternative suggested in the report, which does not exclude any other method of improving finance, would be the establishment of a Central Fund on somewhat similar lines to those of King Edward's Fund for London. The proposal, rejected at Sheffield two years ago, has yet much to commend it, although it may be years before such a fund could grow to any considerable dimensions, and time is of the essence of the problem. In one way or another the need for additional hospital accommodation, which in certain areas is very acute, must be met, and careful study of Dr. Menzies's report will be of material help to those who are concerned to raise the money. The report this year also contains a series of valuable essays on various aspects of hospital administration, one of which we print on another page. In this essay Mr. N. Bishop Harman sets out the claim for the general hospital as the ideal unit of organisation. There is, he argues, no justification for separate hospitals for disease of the nose, throat, skin, heart, rectum, urinary organs, for cancer cases, or for radiological treatment. Special hospitals run the risk of one-sided growth through loss of contact with general medicine and surgery or from failure to know what other branches of medicine are doing. The issue is one which needs to be clearly thought out in contemplating the addition of hospital beds in the near future.

[1] Voluntary Hospitals in Great Britain, excluding London. Sixth Annual Report, for the Year 1924. By F. N. K. Menzies, M.D., F.R.C.P.E., D.P.H., Director of Hospital Services, Joint Council of the Order of St. John and the British Red Cross Society. With a Foreword by the Hon. Sir Arthur Stanley, Chairman of the Joint Council. 19, Berkeley-st., London. 1s. 6d.

CHIROPRACTIC.

THE first essential in the practice of medicine is the honest attempt to make an accurate diagnosis. Licensing bodies throughout the world prescribe a prolonged course of study, after a stiff entrance examination, with a view to producing a certain standard of diagnostic ability amongst those who are to have the care of the sick. In his presidential address last Monday to the Medical Society of London (summarised on page 807), Sir Holburt Waring ruthlessly laid bare the exiguous curriculum of many of the osteopathic and chiropractic schools in America. It would appear that many of these schools make no condition of entrance save the ability to read and write; they prescribe a mere 18 months of study prior to granting a doctorate of osteopathy or of chiropractic. The type of manipulator thus produced preaches the utterly unscientific doctrine of displacement of vertebræ with direct pressure on nerves and vessels as a result. There is a more enlightened school which describes the osteopathic lesion as an immobilisation of the joint outside its position of normal movement, and which attributes the resulting ills to irritation of the sympathetic. The growth of these two schools, whilst undeniable, need give rise to no serious anxiety unless there is failure on the part of the medical curriculum itself to recognise the value of manipulation in the treatment of pain, local or referred. We know of only one general hospital at which a class of students is taught the technique of joint manipulation, and attendance at this class is not compulsory. In cases in which manipulation offers a chance of relief this can now be obtained only at the hands of a small group of qualified practitioners, and relief, therefore, tends to be sought in unqualified channels.

Annotations.

"Ne quid nimis."

RESEARCH IN THE MEDICAL SERVICES.

OUR issue this week opens with an address, entitled as above, and delivered before the appropriate Section of the Royal Society of Medicine by Sir William Leishman on Monday last. The Director-General, A.M.S., points with confidence to the opportunities enjoyed by the officers in his and in the sister Services, for contributing to the medical wisdom of the world both by coöperation and by individual labour. His words in the latter respect, with regard to the planning of work, are wholly admirable; especially does he inculcate that self-criticism which will go far to prevent premature enunciation of theories, a proceeding which is unfortunately followed by personal disappointment or resentment for the would-be discoverer, while it is woefully embarrassing for all workers along the same lines. Sir William Leishman's counsel is designed to create a fine individual worker who shall contribute to collective research. Alterations in the conditions of service in the R.A.M.C., which took effect under Sir John Goodwin some five or six years ago, with the active coöperation of Sir William Horrocks and the present Director-General, have made it possible for sound scientific workers to attain to positions in the Service of proper trust and emolument, so that the great scope for original labour in tropical and preventive medicine offered by the sphere of duty can be properly taken advantage of. The reform is bearing fruit now, while the urge of scientific enterprise has manifested itself also in the Navy and the Air Force. In all the Services there must arise difficulties due to isolation, to change of station, and to the daily pressure of routine, but in all of them there is a spirit abroad surmounting the obstacles, and that it is the spirit rather than the provision of material appurtenances which counts is sufficiently shown by past records. The zoological-pathological work of Manson and Ross was accomplished largely while carrying on their arduous duties, and with a similar disability Sir Leonard Rogers found time to reverse the figures of cholera mortality. Sir David Bruce, with many patients but no laboratory save what he could construct for himself, found the germ of Malta fever and initiated a campaign which added a battalion to the effective strength of the Army; after which he, with the devoted assistance of his wife, went on to discover the relations of the tsetse-fly to sleeping sickness. Sir William Leishman himself, while engaged in the duties of his office, discovered the cause of kala-azar, and Sir Percy Bassett-Smith, as a naval officer, showed the Navy how to escape the menace of scurvy. Last week we published a paper read to the International Congress of Aerial Navigation at Brussels by Group Captain Martin Flack, in which the relation of stable nervous control to flying efficiency was fully discussed, and the elaborate work there indicated, which has to be undertaken for the assessment of a candidate for flying duties, demonstrates the high range of scientific accomplishment to which officers in the Air Force Medical Service must to-day attain if they are to discharge their duties. Medicine may look confidently to the Services for competent and zealous recruits to medical research.

THE TEACHING OF HEALTH.

THE Royal Sanitary Institute was recently responsible for a National Health Week, when nearly 400 cities and towns of the United Kingdom joined in the campaign for rousing a sense of personal responsibility for health. Such a health week has usually as one of its attractions popular lectures on health matters, and there seems to be an increasing demand for public health propaganda by the spoken word. In view of this it seems important that the principles underlying the health talk should be fully understood, for there is a certain amount of danger attached to faulty method. It is interesting to note that education in general relies largely on the spoken word, and that despite the high level attained by modern advertising business still has to depend to a large extent upon the glib salesman. while health propaganda is still mostly a matter of poster, pamphlet, or picture, to the neglect of the most valuable medium afforded by speech. The National Tuberculosis Association of America has realised some of the difficulties attendant on the use of the spoken word, and in a recent little book [1] Dr. Iago Galdston has analysed these difficulties and set down certain rules for the guidance of the health teacher. The speaker in the first place should be carefully chosen and diligently trained, and it must be borne in mind that one who can effectively lecture to a group of city merchants may fail lamentably before a class of school-children. The choice of vocabulary must be strictly made with the elimination of all technical words, and a pleasantly carrying voice is as important as a forceful personality. The subject matter of health talks presents more difficulties than are at first apparent; the available information must be abstracted, defined, and arranged in such a manner that it can be adapted to the age, social, or sex group for which it is intended. It is to be remembered that in these days of the universal newspaper most audiences will have a smattering of recent information on health matters. A lecturer on cancer, for example, will be expected to give an account in simple language of any recent discoveries in this field and he will lose some of the effect of his appeal if this be omitted. Health teaching is not the same as health preaching, and the untrained lay speaker who recites a set of rules will, in general, prove ineffective, for members of the average audience demand to be told the reasons why they should change their ways and do this and avoid that. The audience to which a health talk is being given must always be carefully considered, and the set lecture delivered alike to factory-hands, school-teachers, and working-class mothers is likely to be of less value than if it were skilfully adapted to suit the situation. The set lecture written out in full is also to be condemned; with the main points before him the successful lecturer will develop his theme according to immediate circumstances. The long talk and the series of talks will differ considerably from the short talk, and here again skilful adaptation will be necessary for success. The question of the adjuncts of a lecture have also to be considered; in general the distribution of pamphlets should take place after the health talk, and other illustrative material such as charts, slides, and films must be chosen to harmonise with the subject, both in substance and in treatment. When slides are used the lecturer should be careful to speak *with* the pictures rather than *about* them, for this avoids the obvious handicap of a rapidly shifting attention on the part of the audience. When films are used brief introductory remarks and then the picture, followed by some 10 or 15 minutes' talk emphasising certain points, will be found the best plan. Object talks, including blackboard drawings, have certain uses, but here, even more than elsewhere, the lecturer will need special training. Dr. Galdston's little book includes an account of how a broadcasted health talk should be arranged. The necessity of a striking introduction is obvious, and a talk in clear-cut, short, simple sentences will enable anyone tuning in during the middle of the talk to understand what it is about. Broadcasting opens up a new avenue for the effective promotion of public health, but certain points in the technique require close attention. Some of the suggestions made here may seem trite and unnecessary, but with the new powers under the Public Health Act enabling local authorities to spend money on health propaganda there is some danger that the teaching of health may be looked upon as a simple off-duty occupation for junior officials in the health departments. The effective use of the spoken word in health propaganda has undoubted value, but care must be taken to master some of the esssential details of what is certainly a highly specialised art.

PERSPECTIVE IN X RAY INTERPRETATION.

Dr. William Cotton has endeavoured to apply the laws of perspective to the art of radiography, and he gave a demonstration on the subject at the recent International Congress of Radiology, the substance of which he has now reprinted. By these laws we are enabled to represent accurately on a plane the appearance of triply extended objects as seen from a point known as the centre of vision. The author considers that in radiography the focal spot of the X ray tube is the centre of vision, and in order to obtain a correct interpretation of a radiogram the observer must stand in the same position relative to the film as the focal spot when the exposure was made. If this position is adopted, then by the same laws of perspective the view of a subject seen on the fluorescent screen is a false or reverse one. This picture, however, is the only one possible in existing radiographic methods. In view of the valuable information which the fluorescent screen reveals, it would appear desirable to adopt methods for examining radiographs which give the same picture of a subject as seen on a screen. By the same picture is meant that the parts of the radiogram appear in the same positions relative to the observer as they would appear on a fluorescent screen. An attempt to obtain this view is complicated by the extensive use of both positive and negative radiograms, but the difficulty is removed by marking the side of the film placed next the subject during exposure. When the film is viewed through this side a negative picture is seen if the above convention is adopted. The positive, corresponding to the fluorescent view, is the mirror image of the former and is obtained by viewing the film through the unmarked side.

Owing to the local nature of many radiograms, the observer has not the advantage as in photography of knowing when the image is erect, and it is usual to make some mark on the film, the position of which relative to the subject is known. In the picture seen on a fluorescent screen those parts of the subject nearer the observer are more sharply defined than those more remote, and in this respect the screen picture corresponds to the photograph. On the other hand, the parts of the subject further from the screen are magnified, whereas in the photograph more remote parts appear diminished in size. This distortion observed on the screen and radiogram is obviously due to the use of a cone of illumination, part of which is transmitted through the subject to the film and is independent of the position of the observer. For this reason, therefore, it is not to be expected that a radiogram will furnish directly accurate data concerning the relative dimensions of the different parts it portrays. However, by placing the affected part as near as possible to the fluorescent screen a truer idea of its dimensions may be obtained. To ascertain the position of a foreign body, two radiograms are taken by the usual stereoscopic method. Following the above convention the picture obtained when the X ray tube is moved to the right may be termed the right-eye picture and that for the corresponding shift to the left, the left-eye picture. Correct relief can only be obtained from a stereoscopic pair when the right-eye views the right-eye radiogram and the left eye views simultaneously the left-eye picture. The methods by which the two pictures are superposed may be divided into two classes. In the first, of which Brewster's lenticular stereoscope is an example, each eye views its appropriate picture or its enlarged image. In the second, right and left eyes view mirrored images, which correspond respectively to right and left-eye pictures. The Wheatstone stereoscope is of this type and it is clear that to obtain correct relief, from the point of view of the fluorescent screen, the right-eye view must be placed on the observer's right hand and the left-eye view on his left. Both views must be so placed that the sides of the films, which were originally in contact with the subject, face the observer.

---

[1] Health Speaker's Handbook. New York: National Tuberculosis Association, 370, Seventh-avenue. 1925.

The application of the principles of perspective to radiography, as suggested by Dr. Cotton, is useful in that it stresses the importance of adopting systematically the same position relative to all radiograms. It is in his choice of a position corresponding to the focal spot that we differ from Dr. Cotton. This position leads to a picture which is the reverse of that seen on the fluorescent screen, and thereby introduces a complication which is avoided in the method of examination outlined above.

THE RELIEF OF LEEDS UNIVERSITY.

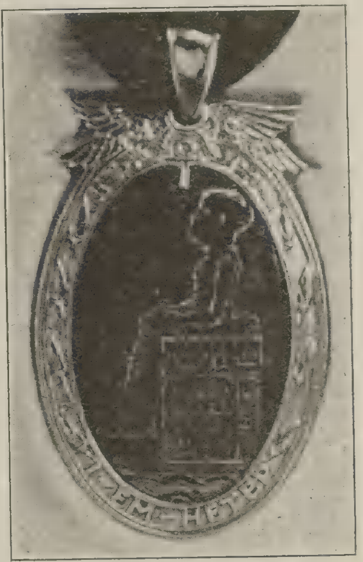
THOUGH certain authorities have doubted whether stone walls a prison make, and all have agreed that they do not make a university, it cannot be denied that stone walls are an important predisposing cause of both types of institution. Scattered wooden buildings make a poor prison and are inappropriate to a seat of learning. The rapid growth of Leeds University has made it necessary to carry on much of its work in temporary structures and transformed dwelling-houses; but in the course of time such conditions have become increasingly irksome, and the University is rightly pleading for relief. Present conditions are hardly tolerable, and expansion is impossible until new and larger buildings can be put up. The occasion of the appeal is timely; the coming of age of the University coincides with the jubilee of the Yorkshire College of Science, which was one of the three bodies whence it sprang. Of the many factors which brought this College into being the most important were the increasing public appreciation of the value of education, and especially of scientific and technical education, and the growth of the mechanics' institutes. The motives of the promoters were utilitarian; they wanted to increase industrial prosperity, but even at the inauguration there were those who took a wider view. On this occasion Dr. Lyon Playfair said:

> "The object of technical education, even in a technical school, is not to teach men how to use spinning jennies or steam hammers, but it is to give a cultured intelligence which may be applied to work in life, whatever that may be . . . The ultimate effect of this may be that you may evolve a wider and more comprehensive college for higher education."

It is said that when the College opened its doors in 1874 only one student, a coal miner, appeared on the first day, and that two more days elapsed before he was joined by a second; but the three original professors were Sir Arthur Rücker, Sir Edward Thorpe, and Prof. Alexander Green (all of whom became Fellows of the Royal Society), and the wisdom of choosing such men soon bore fruit in the success of their undertaking. It was not long before they came to the conclusion that their efforts could not attain a maximum of usefulness until the curriculum was expanded to include literary study, and in 1878 this change was made and the words "of Science" were deleted from the name of the Yorkshire College. About this time the Leeds School of Medicine, which had been in existence for nearly 50 years and had achieved something of a reputation, began to wish for university status, and it joined forces with the Yorkshire College in 1884 in the hope that the joint college would be admitted to the Victoria University. In 1887 the hope was realised, and Yorkshire College joined Owens College and University College, Liverpool, in a federation. In 1903 this federation was dissolved, and in 1904 a Royal Charter made Leeds a University. It is hardly necessary to describe the fortune of the venture. The academic staff has grown to include 268 persons; there are some 1700 men and women students, 320 of whom live in University hostels; and there are 42 departments of study grouped in the four Faculties of Arts, Science, Technology, and Medicine. Such an institution as this can do invaluable work for its county and its country, and yet, unlike other universities, it has hardly received the financial support which its services deserve; and although ends just meet on the present revenue of £173,000 per annum (33·4 per cent. of which is from Government grants and 17·2 per cent. from local education authorities), a special effort is needed if the University is to be freed from its present cramping and expensive circumstances. In our correspondence columns we publish an appeal for the medical school, a school which is associated with the names of men, living and dead, who have been leaders of our science. It will be regrettable if appeals do not meet with a worthy response.

I-EM-HETEP.

THE medallion which we reproduce was presented on Oct. 8th to the Reading Pathological Society by Sir Stewart Abram, an ex-president of the Society, to be the President's jewel or badge, and is of interest since, instead of the somewhat hackneyed figure of the Greek god Æsculapius, it represents the Egyptian Deity of Medicine, I-em-hetep or Imhotep, whose name signifies "he who cometh in peace." This famous Egyptian lived about 2900 B.C., and was a learned and many-sided man. He was Prime Minister to a Pharaoh of the Third Dynasty named Zoser. Further, he was a distinguished architect, and built the earliest pyramid known to history, the Step Pyramid of Sakkarah. Above all, however, he was noted as a physician, and he so impressed his fellow-countrymen with his skill in the healing art that he was eventually acknowledged throughout Egypt as the Deity of Medicine. In his honour temples were erected in various parts of the country, and to them flocked patients from far and wide. Many miraculous cures are reputed to have taken place at his shrines. The jewel presented by Sir Stewart Abram consists of a pendant in hand-chiselled gold and enamel, designed and made by Mr. Omar Ramsden, of London. The oval plaque of enamel shows the image of the god, which is based on an exquisite early bronze statuette in the Wellcome Historical Medical Museum. The god is shown in profile, seated on a golden "throne of knowledge," while his feet rest upon a footstool representing the solid earth, which is surrounded by a green band symbolising the cultivated strip of land watered by the Nile. The latter is in heraldic blue and white, flowing by in full tide, whilst the background shows the blue sky of the East. The delicately wrought frame is surmounted by a double-headed and winged serpent from which is suspended the Egyptian "ankh," the symbol of life. The border is made up of lotus buds springing from a lower space inscribed with the name "I-Em-Hetep." At the back is engraved the following sentence: "George Stewart Abram commanded me to be wrought for the Reading Pathological Society, in October of the year of our Lord MCMXXV." At the Congress of the History of Medicine, held at Geneva in July last, a paper on I-em-hetep, the Egyptian Deity of Medicine, was contributed by Dr. J. B. Hurry, of



Reading. To the Reading Pathological Society will fall the honour of having been the first in this country to recognise the claims of I-em-hetep to be regarded as the Deity of Medicine. "I-em-hetep is," to quote the late Sir William Osler, "the first figure of a physician to stand out clearly from the mists of antiquity."

ALCOHOLISM AS AN INTERNATIONAL PROBLEM.

International movements are always suspect; it is often suggested that they are a kind of sport which enables reformers to visit foreign countries and hold enjoyable meetings. That the internationalism of the campaign against alcoholism is of real significance was the thesis of a lecture by Dr. R. Hercod, of Lausanne, before the Society for the Study of Inebriety on Oct. 13th. Certain countries, he said, have newly taken up vine growing; others have reduced their consumption by legislation or propaganda; economic depression has reduced markets; and the result of these things is a crisis in the wine-producing countries which has forced the growers to seek new custom. A French Minister for Agriculture encouraged the people to drink more wine on the grounds that this "temperance beverage" was really the best weapon in a serious fight against alcoholism (although an average annual wine consumption of 30 gallons per head suggests that the French population was already doing its duty); but however much sympathy may be felt with such enthusiasm, it is less easy to condone the methods adopted by France and Spain in forcing the importation of their produce on foreign countries. Iceland has been obliged to except Spanish wines from her prohibition laws because Spain could starve Iceland by refusing to admit her exports of fish, and Norway has suffered in much the same way at the hands of France. German breweries have considerable stakes abroad, and they and their methods are implanted in the Far East; and Scotch whisky is not without its influence on distant peoples. According to Dr. Hercod, Africa is suffering from a veritable scourge of alcoholism, which is the outcome of Western civilisation and which is inadequately controlled by the Convention of Saint-Germain-en-Laye. In partly Moslem countries the influence of religion is being overcome, and everywhere the lands which are producing more alcohol than they can consume are pressing their produce on others, in ways both legitimate and illegitimate. The support of the press has greatly helped the international campaign against prohibitive legislation, which has therefore been as successful as might be expected; but it is not merely in reaction against the activities of the liquor traffic, Dr. Hercod considers, that the cause of temperance will be helped by international coöperation. More information is needed on the experiments, both individual and social, of other countries, and the United States has lost a great opportunity by failing to organise a systematic and continuous investigation of the facts of prohibition. A strong educative campaign must be based on truth, and as yet there are gaps in scientific knowledge which should be filled. There are, for instance, discrepancies between the results of Dr. H. M. Vernon and Prof. E. M. Widmark, to name two workers only, and such discrepancies should be cleared up. Though it may be possible, even now, to come to an international agreement on the manufacture and distribution of alcohol on a smaller scale, it will be impossible to contemplate its total suppression so long as the population in general is unwilling to admit such a measure. Study of the propaganda methods of other countries, and especially their work in schools, is most valuable, and the International Bureau Against Alcoholism, of which Dr. Hercod is director, will do much to help. All who are imbued with the scientific spirit will approve the dissemination of the truth, about alcohol or anything else, but it is evident from the increasing stress laid by temperance workers on the social side of their work that scientific facts do not always impress the public. Alcohol has not been damned by being called a narcotic—for a narcotic is just what most people most enjoy. It has been truly remarked that "Mankind has never needed a stimulant, but rather something to take the edge off things."

CRITERIA OF PATHOGENICITY.

The time-honoured criteria for the identification of a microbe as pathogenic are those familiarly known as Koch's postulates. The difficulty in applying these criteria lies in the fact that the majority of pathogenic organisms do not produce in experimental animals a disease exactly identical with that which they produce in man. This holds not only for organisms whose rôle in human disease is still open to doubt, such as Pfeiffer's bacillus, but also with the most firmly established species, whose pathogenicity has been proved both purposively and accidentally upon the human subject, such, for example, as the typhoid and cholera organisms. Consequently, in attempting to prove the relationship of a given organism to a supposed disease the experimental demonstration often breaks down over this point, and this is the crux of the difficulty which lies in the way of proving or disproving the truth of claims which are constantly put forward. In a recent paper[1] Dr. W. M. Crofton suggests that two criteria may be safely substituted for the third of Koch's postulates. The first is that if a vaccine from a given organism will reduce the morbidity and mortality of a certain disease, then the organism composing the vaccine is the one which causes the disease, and, in evidence thereof, he cites the case of typhoid vaccine and the incidence of typhoid fever. This contention may be admitted in the absence of direct evidence to the contrary, but it must be remembered that not only are all the factors in play in such a case extremely hard to control, but that non-specific effects in immunity reactions are not uncommon, and in clinical medicine other parallels may be found to the case of small-pox and vaccinia. Dr. Crofton's second contention is even less tenable. He asserts that if in a given disease a vaccine or bacterial preparation produces a reaction—e.g., the tuberculin reaction—which is not obtained with the normal individual, and its injection is followed by amelioration or cure of the disease, then such a vaccine is composed of the causal organisms. He instances his own results with influenza vaccine in encephalitis lethargica, and those of Dr. H. W. Crowe, who claims to have cured cases of rheumatoid arthritis by a *Staphylococcus albus* vaccine prepared from organisms recovered from the urine. Both of these instances are unconvincing, since the association of influenza and encephalitis is very generally agreed to be a negative one, and, further, the present treatment of rheumatoid arthritis by bacterial vaccines, for which considerable success is claimed, is avowedly non-specific, such organisms as *B. typhosus* being frequently used. Whether or no they embody final truth, Koch's postulates cannot be set aside without substituting a habit of extreme and rigid self-criticism in bacteriological research.

HOME SERVICE AMBULANCES.

A legacy of the war was the inception of the ambulance facilities we now enjoy in this country. Before 1914 in only a few of even the great cities had the municipal authorities established a motor ambulance service. The County of London was still content with the service of hand-propelled wheeled litters established by the police, and it was not until 1915 that the motor ambulance service was inaugurated to deal with accidents. During the war, as everyone knows, splendid work in the provision and maintenance of ambulance service was done through the coöperation of the Order of St. John of Jerusalem in England and the British Red Cross Society, and happily after the signing of the armistice these two organisations decided that the need for their united efforts in the care of the sick had not come to an end. One of the first steps they undertook was the organisation of a national ambulance service for England, Ireland, and Wales. It was to the needs of the rural areas especially that attention was devoted, as in London and the great towns official boards had already begun to provide for the transport of the sick. The Home Service Ambulance Committee, formed under the Joint Council of the two Societies, began, therefore, to set up ambulance stations in various parts of the country, and to-day these number 341, with 34 affiliated stations, making a total of 375. The total number of cases carried since the establishment of the service up to the end of June, 1925, was 312,501. The Committee has just issued a new edition[1] of the register of these ambulance stations, grouped in counties, and to medical men in all counties there has been sent a list showing the stations in their county. Further, all the road scouts of the Royal Automobile Club and the Automobile Association carry a list of stations within their patrol. Wherever possible ambulances are placed in charge of those who by training have acquired dexterity in the handling of the sick and injured, nor is the handling of the vehicle itself of minor importance, for unskilful driving may gravely prejudice the patient's chances of recovery. The Order of St. John and the British Red Cross Society have a great body of trained members who voluntarily and gladly give their services. Maintenance costs are met in different ways according to local circumstances. In the majority of cases a charge is made for the use of the ambulance, calculated to cover the actual running expenses, with a margin sufficient to allow for remissions in necessitous cases. By such efficient ambulance service the sick can obtain a standard of treatment which might be impossible in or in the neighbourhood of their own homes, and in addition the safe transport of convalescing patients from large hospitals to smaller or at all events less expensive institutions can do much to relieve the pressure on the nerve centres of our hospital system.

PARATYPHOID TRACED TO ICE-CREAM.

IN his report for the month of August Dr. G. P. Kinloch describes an outbreak of paratyphoid fever. Investigation revealed the fact that 21 Aberdeen cases were associated with the outbreak, and, further, that two girls from Glasgow, who had been on holiday in Aberdeen from July 17th to the 30th, had sickened of paratyphoid fever in Glasgow on August 2nd and 5th, respectively. Previous to 1924 paratyphoid fever had been absent from Aberdeen for four years, but cases were notified during the present year on May 7th, June 20th, July 10th, and August 5th and 9th. These cases, as far as could be determined, were separate and distinct from the 23 cases of the outbreak. In endeavouring to trace the source of infection, the milk-supply could be excluded, as the 20 families concerned were supplied by 13 dairies. After full inquiry it was ascertained that the one common article of food consumed was ice-cream, obtained from a particular shop on July 20th. As the patients sickened on or about August 4th, the incubation period of the disease could be put at about 15 days. In the shop in question about six gallons of milk are daily converted to ice-cream, the milk being brought to the boil, cornflour, &c., added, and then the mixture again brought to the boil, and when cold introduced into the refrigerator. The time which elapsed between the infection of the ice-cream and the outbreak made it impossible to find out exactly how the ice-cream had been handled and disposed of on the day in question. Full bacteriological investigation of the workers in the shop was carried out. Both the shopkeeper and her mother had suffered from typhoid fever a long time ago, and their blood agglutinated to *Bacillus typhosus*, but not to *Bacillus paratyphosus*. The shopkeeper's son had agglutinins both to *Bacillus typhosus* and to *Bacillus paratyphosus*, but he had been inoculated against both varieties in the army in 1917. Samples of blood from the three employees contained no agglutinins, and the specimens of fæces and urine from all six persons engaged in the shop were negative. There was no evidence that the milk from which the ice-cream was made was infected. It was obtained from one of the largest milk retailers in the city. It is estimated that 360 customers might be supplied daily with ice-cream from this shop, but so far as is known only 23 cases of infection occurred. There were no deaths, but some attacks were severe. In view of the fact that during July there was an outbreak of food-poisoning in Aberdeen, affecting some 500 persons, traced to a bacillus of the Gaertner group, Dr. Kinloch proposes to publish a more detailed report of both outbreaks later.

THE PANEL CONFERENCE AND THE OPHTHALMIC SPECIALIST.

THE Annual Conference of Representatives of Local Medical and Panel Committees will meet in the Great Hall of the British Medical Association next Thursday, when there is a very full agenda paper. The most important, although not the most controversial, matter which will come before this Conference is the new arrangement made in regard to ophthalmic benefit for insured persons. As the culmination of a long series of negotiations between representatives of British ophthalmologists, the Ministry of Health, and the Association, there has now been drawn up a list of 600 practitioners throughout the country who are regarded as ophthalmic specialists and who are willing to treat insured persons at a uniform fee of a guinea to cover each complete case of refraction. These practitioners have obtained access to the list by virtue of holding certain ophthalmic appointments, of having made a special study of ophthalmology, or of being recognised by fellow practitioners as having special proficiency and experience. Their fees will be paid out of the surplus sums available for additional benefit revealed at the second Approved Society valuation. Most of the smaller societies eligible to join the scheme have come in, bringing with them a million and a half insured persons. The larger societies, although not hostile to the scheme, are ineligible to join until next year. The actual procedure is that any panel practitioner, finding the condition of a patient such as to require ophthalmic treatment, shall at his patient's request furnish him with a recommendation in writing that such treatment shall be obtained. The insured person then procures from his society the necessary authority to visit one of the ophthalmic surgeons on the approved list. The scheme represents not only the death-knell of an attempt on the part of lay bodies to institute a kind of optical benefit outside the medical benefit provisions of the Insurance Act, but is the first embodiment of a specialist service within the Insurance Acts. No doubt other specialist services will follow in due course now that official recognition has been given to the doctrine that insured persons are entitled to treatment by fully qualified persons.

THE SANATORIUM AND AFTER.

THE after-treatment of ex-sanatorium patients is one of the most urgent and elusive problems which medical and social science has to face. A scheme to provide industrial employment in hygienic workshops, started in London two years ago, has given results sufficiently encouraging to merit attention from all who are dealing with tuberculosis care and after-care. A public meeting held last week in Holborn Town Hall in support of the more general provision of such workshops is reported fully on another page. From the strictly medical standpoint it is admitted that the combination of sanatorium, settlement, training centre, and workshop offers the ideal conditions for after-care, but such settlements can only deal with a fraction of the tuberculous population. While any workshop scheme has its inherent difficulties, the success of the London experiment known as Spero Leather Workers has surprised those who have watched it most closely. The improved health and happiness of the workers, consequent on their feeling of rehabilitation in industry and of their ability to maintain themselves, and perhaps a family, has exceeded expectation. During the 30 months since the workshop was started, absences on account of health have not exceeded 4 or 5 per cent. of the total time, although all the workers are ex-sanatorium patients; and this absence is covered by a scheme of sickness benefit. It is rather on the economic side that the difficulties lie. The tuberculous worker obviously cannot earn a living wage during his period of training or for some time after, and the distribution of manufactured goods on a small scale presents difficulty. It would be fatal to the success of any scheme to allow the standard of living of the workers to become inadequate, and steps have to be taken to supplement their income where necessary. At present the Central Fund for the Industrial Welfare of Tuberculous Persons is undertaking this responsibility. The outstanding need appears to be for schemes of employment providing work which does not require a prolonged period of training, such as repetition in workshops fitted with the necessary machinery or other work of unskilled or slightly skilled order. We hope that the publicity given to Spero Leather Workers will result in experimental schemes being started on other lines. Unfortunately the municipal workshop idea worked out by the late Dr. F. Stanley Tinker (THE LANCET, Feb. 21st, 1920) never came to fruition. It remains true, as he then said, that the value of the labour of tuberculous subjects has not yet been worked out. If properly managed it should, he thought, cover the cost of wages and even in time produce a small profit. This has been the case in the London experiment.

IMMUNISATION AGAINST SCARLET FEVER.

IN a communication recently made to the Minnesota State Medical Association Dr. W. Colby,[1] of the Miller Hospital Clinic, St. Paul, reported that he had carried out active immunisation with detoxicated toxin of 132 children, aged from 2 to 14 years, and 16 nurses, who all presented positive Dick reactions. Sodium ricinoleate was used as the detoxicating agent, which, as Dr. W. P. Larson, of Minneapolis, has shown, possesses the power of neutralising bacterial toxins without altering their immunising properties, as he proved by successfully immunising animals against diphtheria and tetanus by this agent. The technique of the procedure consisted in the addition of an equal volume of a 2 per cent. solution of sodium ricinoleate to the toxin, when the final dilution equalled 4000 skin-test doses per c.cm. Thus prepared the toxin was allowed to stand at least four hours before injection. One injection only was given, the dosage ranging from 500 to 4000 skin-test doses. No general reactions occurred, and there were only negligible local reactions, consisting in erythema and slight induration, which disappeared within 36 hours. Immunity was established in direct ratio to the amount of toxin given. In order to increase immunity still further the dosage was safely increased to 6000–8000 skin-test doses. For children under 10 years of age observations showed that 4000 skin-test doses were sufficient. In older children and adults a higher dosage was required, as was shown by the low percentage of immunity (37·5) in the case of nurses in whom only 2000 skin-test doses were used. In the subsequent discussion, Dr. Larson remarked that sodium ricinoleate was nothing more or less than a highly purified castor-oil soap. The advantages of neutralising the toxin with this substance instead of with antitoxin, as in the ordinary toxin-antitoxin mixture, was that antitoxin tended to sensitise the child to horse serum. Since it was possible to neutralise the toxin effectively with castor-oil soap and possibly to effect immunisation with one dose, the main objection to active immunisation against diphtheria and scarlet fever would be removed.

DIFFICULTIES AND DANGERS OF INSULIN.

THE unique value of insulin in the treatment of diabetes is known to every newspaper reader in the world, but its drawbacks are not fully recognised even by those who have to use it. Many first-class research workers have, however, been energetically testing it under all conditions since it was first given to the world by Dr. F. G. Banting, and the mass of their results has laid bare most of its dangers and made known the most efficient precautions against them. Those who attended the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine that was held on Tuesday last had the privilege of hearing the latest results of some of the most eminent workers in this branch of therapeutics from the workers themselves. Dr. George Graham, who chose the subject for his Presidential Address, is well known as the author of many works on diabetes and allied conditions, and has a specialised experience of the disease that extends over many years.

Dr. Graham stated first of all that insulin, which is undoubtedly a very important discovery, does not cure diabetes, but so effectively counteracts as to enable the patient to take his normal place in social life. Very few who are treated with it remain invalids, and still fewer die entirely unaffected. He analysed 85 cases that had come under his own experience during the last two years at St. Bartholomew's Hospital, and showed that the 17 deaths were mostly in-patients who had never had insulin before they entered hospital, and in whom the diabetes had caused organic lesions that overcame the natural resistance even when the disease was counteracted. The large majority of patients treated with insulin were able to leave hospital after a few months and continue the treatment themselves. The difficulty here is to keep the blood-sugar normal after discharge. The normal in most people is below 0·1, but it is difficult to get it as low as this without causing discomfort from an overdose of the drug, while a high sugar content lowers the natural resistance to it. Hence, it was necessary by diet to reduce the sugar as much as possible without insulin. He exhibited several interesting charts and made some remarks on taking blood samples and on the regulation of treatment by post, a very interesting side-issue; he also gave an illuminating series of examples of the method of securing a good insulin "balance." Hypoglycæmia sometimes results if the dose is too high, but it is rarely very dangerous and the symptoms decline when sugar is administered. Curiously enough, the insulin requirement is often decreased after an attack. Another difficulty is that an intercurrent infectious complaint will send up the blood-sugar; if it is severe there is a danger of giving too much insulin. By taking urine samples every three hours and regulating the extra doses accordingly it is possible to keep step with the increased sugar content. Very large doses are often given with safety when the blood-sugar rises from this cause, sometimes up to 200 units. The danger comes when the patient begins to recover, and sugar should be kept ready against symptoms of hypoglycæmia.

Dr. R. D. Lawrence followed the President with some very interesting comments on the effect of exercise in lowering the sugar content. He quoted the case of a gardener who, on increasing his work at the beginning of summer and also taking up cricket, suffered from mild hypoglycæmia; 4 units decrease in the morning dose, which had been 10, restored this balance. When he resumed a more sedentary life his blood-sugar again rose. He is now learning to keep his balance according to his work output. Sunday tennis produced the same effect in another patient.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLXIII.

TREATMENT OF HYDROCELE, HÆMATOCELE, VARICOCELE, AND SPERMATOCELE.

Consideration of the treatment of these four conditions involves a brief discussion of their ætiology and differential diagnosis. It is clear that where the scrotal abnormality occurs as the result of the presence of some other focus of disease in the body, it is this primary lesion which calls urgently for treatment. Again, should erroneous diagnosis of these conditions be made, treatment directed to their cure is more likely to result in harm than benefit to the patient.

I. *Hydrocele.*

This is the only one of these four conditions not essentially male, as it is occasionally met with in the labium majus, especially in little girls, as *Hydrocele of the Canal of Nuck*, when its treatment is that of excision of the sac through an inguinal incision.

Various types of hydrocele are met with in the male.

Diffuse Hydrocele of the Cord is a rare multilocular cystic condition of the whole scrotal extent of the spermatic cord, often extending up through the inguinal canal into the abdomen; and the treatment consists in dissecting the mass away from the cord, by no means an easy task.

Hydrocele of an Unobliterated Processus Vaginalis (congenital hydrocele) is a condition met with in young children and usually only diagnosed when there is some coexistent inflammatory condition of the peritoneal cavity, such as tuberculous peritonitis, which causes fluid to be exuded and gravitate into the vaginal sac. Congenital hernia is usually also present unless the opening in the neck of the sac is too small to allow of the passage of bowel or omentum, but is a fruitful source of misdiagnosis, the best point in differentiating the two conditions being the slowness with which the hydrocele fills and empties and the absence of resonance in the fluid swelling. In a young child both will be translucent. Treatment consists in excision of the sac through an inguinal incision as for hernia; should tuberculous peritonitis coexist operation should be put off till this has been cured, as not only is there grave danger of a tuberculous sinus following operation, but a spontaneous cure may result.

Encysted Hydrocele of the Cord presents as an ovoid swelling in or just below the inguinal canal; if in the canal it may be mistaken for a bubonocele but has no expansile impulse on coughing, and can often be drawn down out of the canal by gentle firm tension on the testicle and cord, when the upper limit of the mass can be defined. Rarely chronic suppuration in the course of the cord, following gonorrhœa or tubercle, may cause a similar pyriform cystic tumour. Treatment consists in cutting down on the swelling through an inguinal incision and dissecting it off the cord, a difficult task since the membrane is thin and friable.

Hydrocele of the Tunica Vaginalis (hydrocele) may result from effusion into the tunica vaginalis secondary to some disease of the testis, or obstruction to its venous return, or may be the result of primary irritation of the lining membrane of the sac. It can be diagnosed by its translucency and tapering upper end.

Secondary Hydrocele may result from (1) acute or chronic inflammation of the testes or epididymis, as in gonorrhœa, tuberculosis, or syphilis; or (2) follow on a testicular tumour. In the acute cases there is pain, and examination of the testes and adnexa after "tapping" the hydrocele reveals that they are enlarged. The condition may also be present, as a bilateral affection, in cases of ascites due to advanced cardiac and renal disease, carcinoma of peritoneum, retroperitoneal tumours, and chylous ascites (when the hydrocele fluid is also milky), due to lymphatic obstruction in filarial elephantiasis and blockage of the thoracic duct. In all these cases treatment must aim at the eradication or alleviation of the primary disease, no local treatment other than tapping being indicated.

Primary or Idiopathic Hydrocele can only be safely diagnosed when the foregoing conditions, and the possibility of a hydrocele in the fundus of a hernial sac, or even an irreducible hernia, have been eliminated. Treatment of the condition is operative and should, except in very old or debilitated patients, aim at effecting a radical cure by removal of the secreting membrane, though tapping may often be necessary as a diagnostic step. The patient should be seated or, better, lying on a bed or couch for this operation.

Tapping.—The position of the testes having been ascertained (usually by touch and the patient's sensation, though transillumination may afford valuable indication of its position), the pyriform scrotal swelling is grasped in the palm of the hand, and the penis being held away by the thumb the skin is made to stretch tensely over the mass. The scrotum is now painted with 2 per cent. iodine in spirit, and an area on the front free from veins being selected, a sterile trocar and cannula are plunged sharply in, the trocar withdrawn, and the fluid allowed to escape through the cannula, the hand being used to press out the fluid toward the cannula. The trocar needs plunging sharply through the tense skin and tunica, both of which it can be felt to pierce, and then a sense of loss of resistance is encountered as it enters the fluid. The common source of inability to obtain fluid is that owing to the skin not being held tense and insufficient force used the trocar slips along the outer surface of the tense tunica between it and the skin, but occasionally it is plunged into the testes, as evidenced by the patient experiencing sickening pain, when it should be immediately withdrawn and reinserted smartly elsewhere.

When no more fluid escapes, the cannula is withdrawn and the opening sealed with gauze and collodion. Some surgeons prior to withdrawal insert a few minims of irritable fluid such as pigmentum iodi, or strong carbolic, which is massaged around, with the object of destroying the endothelial lining and so effecting a radical cure, but this proceeding causes some pain and the results are not on the whole satisfactory, as loculation very often occurs.

Radical Cure.—A short incision is made upwards and outwards from the pubic spine; the scrotal root is to be avoided, as not only is the skin difficult to approximate accurately, with consequent delay in healing, but fouling of the wound, with consequent sepsis, is very liable to occur during the use of the bedpan and urine bottle. The sac of the hydrocele having been exposed in the depth of the incision it is pressed well up into the wound from below and held there while it is incised alongside the cord. A fairly free incision should be made and the stream of fluid directed into a bowl, pressure being meanwhile maintained on the scrotum to empty the sac. The wound is mopped out, and the edges of the sac grasped in forceps, and the whole tunica and testis pulled up through the wound and separated gently from the surrounding cellular tissue, in which all bleeding points must be secured if hæmatoma of the scrotum is to be avoided. This is a serious complication in that it is very liable to infection, with resultant sloughing of the testes; unless, therefore, absolute hæmostasis is assured it is well to drain the scrotum for 24 hours through the lower end of the incision by means of a corrugated rubber drain. Two methods are in vogue for the treatment of the tunica vaginalis, which is now freely exposed, lying on gauze outside the wound :—

1. The simpler method recommended by Winkelbaum can be practised only on thin-walled hydroceles, and consists in everting the testis through the hole in the tunica vaginalis, which is thus turned inside out and secured in this position by a few stitches passing behind the cord and epididymis. The whole rather bulky mass is returned into the scrotum and the wound closed, the object being to secure adhesions between the endothelial lining and scrotal cellular tissue, and so ensure granulation and destruction of the former. The disadvantage of this method is that sometimes the endothelium grows over the cellular tissue and a pseudo tunica is formed, becomes filled with fluid, and recurrence results ; this is the more likely to occur if a small hæmatoma has been present. The percentage of recurrences recorded is, however, small, varying from 1 per cent. to 15 per cent.

2. The surer method consists in clipping away the whole of the parietal portion of the tunica vaginalis, an easy operation, but one accompanied by severe bleeding from the numerous vessels in the tunica. It is advisable to under-run the entire cut margin by a continuous glovers' stitch of catgut to prevent scrotal hæmatoma. The testis is then returned to the scrotum and the wound closed, with drainage for 24 hours if hæmostasis is incomplete.

The wound should be dressed with gauze, retained in position by a suspensory bandage, which acts also as a scrotal support. The patient may get up in four or five days, but should wear a suspensory bandage for two or three weeks.

II. *Hæmatocele.*

The cause of a hæmatocele is nearly always a sharp blow or injury, but may occur as a complication of a malignant tumour of the testis, or in blood diseases such as hæmophilia, scurvy, or severe anæmia. Since in this case local treatment would be disastrous, a blood count should be done if there is any doubt. The tumour presents as a pyriform swelling in the scrotum, which may show subcutaneous bruising, and it can be diagnosed from a hydrocele by the fact that it is not translucent, and from a hernia by having no expansile impulse ; moreover, its upper limit is defined.

Treatment in a recent case consists in supporting the scrotum in a tight suspender, or by strapping, and resting the patient in bed in an endeavour to limit the bleeding. Tapping should, if possible, be avoided for at least 48 hours, as it tends to cause recrudescence of the bleeding ; but it should be practised as a routine after that time has elapsed. After the blood has been withdrawn the affected side of the scrotum should be strapped with zinc oxide adhesive plaster for four or five days, being previously shaved in an adult.

In older cases where clotting has already occurred and thickening of the tunica resulted, the only satisfactory treatment is operation by the inguinal route as for radical cure of hydrocele, and excision of the parietal tunica vaginalis. In very old-standing cases, where extreme thickening and fibrosis of the tunica and scrotal tissues exist, this operation may not be practicable ; in such a case orchidectomy may be undertaken since the testis is usually atrophied and disorganised. The wound should be drained for 24 hours, whichever course is adopted, since oozing from the scrotal cellular tissue is almost impossible to control. Such old-standing cases are not infrequently diagnosed as neoplasms of testis, and it is practically impossible to be certain that a testicular tumour does not coexist with the hæmatocele ; for this reason orchidectomy should be carried out as the operation of choice.

VACCINIA AND VARIOLA.

DR. MERVYN GORDON'S STUDIES OF THE VIRUSES.

DURING recent years the Medical Research Council has given every encouragement to research work on filterable viruses and the diseases for which they are responsible. In the National Institute for Medical Research at Hampstead and at certain suitable centres elsewhere a general programme of investigation is being carried out. The work undertaken by Dr. Mervyn Gordon at St. Bartholomew's Hospital has now been published as M.R.C. Special Report No. 98.[1] Dr. Gordon chose vaccinia for special study because this virus lends itself readily to experimental work, and in the research now published he has certainly clarified and advanced our knowledge of these viruses and introduced methods which may be serviceable in the study of less known or unknown viruses.

The report is divided into three sections, the first of which occupies about a quarter of the book and gives an account of some previous studies of the virus of vaccinia and outlines the scope of Dr. Gordon's own researches. The middle half is devoted to a description of the author's studies of the virus of vaccinia and the last quarter reports some very interesting experiments with the virus of variola. Appended to the report are five instructive photographs, three of which illustrate the generalised eruption in alastrim and varicella, a coloured picture represents the type of lesions obtained in the experimental work on the shaved skin of the rabbit, and a fifth photographs the agglutination of vaccinia virus.

1. *Introduction.*

For most readers the second and third sections of the report will possess chief interest. We shall not therefore attempt to epitomise the already condensed review of previous studies reported in the introduction, but merely call attention to some of the problems connected with the virus of vaccinia on which this scholarly review throws further light. The filterability of vaccinia virus has been a much debated question, but it is clear that the difficulty experienced by many investigators in getting the virus to pass through a Berkefeld filter is not due to the large size of the organism so much as to its adsorption by the material of which the filter is composed. There is no doubt that the rabbit is susceptible to vaccinia and that immunity may be established by about the sixth day after subcutaneous, subdural, intracerebral, or intravenous inoculation of the virus. Serological methods of study have established the fact that in the course of development of immunity three specific antibodies make their appearance in the blood—namely, a virulicidal or antivirulent substance that possesses the capacity of inactivating vaccinia virus in vitro, a precipitating or agglutinating antibody that causes flocculation of the virus, and a complement-fixing antibody. The precise nature of the antibody which has received the cumbersome and somewhat vague name of " virulicidal " is far from clear at the present time ; a curious attribute is revealed by the observation that the virulicidal power of a serum decays faster than the immunity. The precipitating antibody also needs more accurate definition, and the use of the term precipitin would appear to be premature until it has been shown that the substances in the filtrate upon which the reactions depend are really in solution. The complement-fixing antibodies are of constant appearance in response to infection either by vaccinia or variola virus, and the complement-fixing antibody excited by one of these viruses reacts also with the other; but beyond that the reaction is specific. A point of special interest in connexion with passive immunity is the natural transmission of what appears to be a passive immunity from a mother immune to vaccinia to her fœtus. In a case recorded by Béclère, a child proved immune to vaccinia although twice inoculated cutaneously with active vaccinia virus within a month of birth. The blood of the mother and also that obtained from the umbilical cord both contained the virulicidal substance, although the former was the stronger in this antibody. This transmitted immunity is, of course, transient. Dr. Gordon also refers to the successful treatment of patients suffering from variola with the serum of small-pox convalescents, the blood being collected between the twenty-fifth and fortieth day, when the virulicidal power of the serum is at its maximum.

---

[1] Studies of the Viruses of Vaccinia and Variola. By M. H. Gordon, C.M.G., C.B.E., D.M., F.R.S. H.M. Stationery Office. 3s. 6*d*.

The later sections of the report contain important observations on the relations between the viruses of vaccinia and variola, and in reviewing previous inquiries into this question the author remarks that experimental work on serological lines has hitherto been weak on the quantitative side, a defect which, it will be seen, has to some extent been removed by the more accurate technique which Dr. Gordon has introduced. In his work the skin of the rabbit was used as a "reagent" for detecting the presence of vaccinia virus and the test was made quantitative by submitting material to a known degree of dilution before inoculation. He used also the rabbit's skin as a culture medium for providing supplies of this virus by the simple expedient of killing the rabbit and harvesting its lesions at the height of their development. For further details of his technique the original report should be consulted, wherein all experiments are described with exactitude. We pass now to the second section which deals with studies of the virus of vaccinia.

2. *Studies of the Virus of Vaccinia.*

One of the first investigations undertaken was a study of the relative potency of various specimens of calf lymph in use in this country for purposes of vaccination, and after each had been submitted to decimal dilution the degree of their individual capacity to produce vaccinia on the rabbit's skin was determined. We notice from the published protocol that very significant variation existed amongst these lymphs, the most potent being active at a dilution of 1 in 100,000, whereas the weakest only at 1 in 10. This experiment alone points to the urgent need of some compulsory standardisation of vaccine lymphs supplied to vaccinators. As regards their reciprocal immunising action all these individual strains of virus appeared to be identical. Disinfection experiments showed that vaccinia virus is more susceptible to the action of acid than of alkali and that the virus withstands ether comparatively well. But the outstanding feature of the disinfection experiments was the very high value that potassium permanganate appears to possess for destroying in vitro the virus of vaccinia. Experiments on the effect of heat on vaccinia virus showed that an exposure for 30 minutes to 55° C. reduced the active virus by over 99 per cent., but did not destroy it completely. A number of experiments were undertaken to determine the extent to which active immunity to vaccinia can be produced in the rabbit by prophylactic use of this virus after attenuation or destruction by various measures. These proved that a substantial degree of immunity can be produced by vaccinia virus after being heated for 30 minutes at 55° C. provided that the condition of the virus as regards potency was good in the first place and that the dose reached a certain critical or effective strength. This immunity appears four days after subcutaneous injection and thereafter rises rapidly. By the hundredth day a decrease had occurred but a certain degree of immunity could still be detected. Several experiments were designed to study the specific antibodies to vaccinia, and Dr. Gordon has formed the opinion that vaccinia virus excites the production of specific antibodies in the blood of the rabbit after the fashion of ordinary pathogenic bacteria. The complement-fixing antibodies and agglutinins appear to be equally specific for the viruses of vaccinia or variola. Some observations furnished evidence of the presence of lysin in anti-vaccinia serums, but no systematic attempt was made to define the part played by this antibody in immunity to vaccinia. The question as to whether the serum of rabbits immunised against vaccinia is capable of protecting others from this disease was investigated by means of some carefully planned experiments which showed that anti-vaccinia serum which possesses definitely protective properties against the virus of vaccinia may be prepared in the rabbit. One c.cm. of this serum protected against 100 minimal vaccinial doses of virus. Having by means of the cutaneous test of virulence established a sufficiently accurate method of determining the abundance of vaccinia virus in a given suspension, Dr. Gordon proceeded to study the effect on this virus of gravity, centrifugation, and passage through a Berkefeld filter. These experiments definitely proved the virus of vaccinia to be particulate. When a suspension of the virus was allowed to stand 3–10 days in a long narrow tube the top layer was found to be less active than the bottom. The centrifuge reduced the virulence more in two hours than gravity did in three days, but in both these tests the complement-fixation test, being less delicate than the virulence test, failed to detect any difference between the surface and deeper layers. The Berkefeld filter removed the virus so thoroughly from a suspension that all of the three indices of its presence — namely, virulence, complement fixation, and agglutination—although strongly positive before filtration, were thereby rendered negative.

Some particularly interesting experiments are reported by Dr. Gordon on the permeability of various surfaces of the rabbit to the virus of vaccinia. These can be best described in a quotation from the report (p. 87):—

> Employing as chief criterion the production of immunity, evidence has been found that in the absence of mechanical injury and under approximately natural conditions the virus of vaccinia is capable of penetrating the system of the rabbit through the external auditory canal, the ocular conjunctiva, and the nasal mucosa; the last being the most permeable of these three surfaces, since a dose of virus so small as that contained by 0·01 mg. of calf lymph can successfully penetrate by that channel and produce immunity.
>
> When a dose of vaccinia virus of this magnitude, or above, gains access to the nasal mucosa of the rabbit, the animal after an incubation period of 6–8 days develops a condition of acute nasal catarrh accompanied by a mucopurulent discharge which in early stages contains the virus of vaccinia in abundance, and may also contain catarrh bacteria such as pneumococci. This acute stage does not last as a rule for more than a day or two. The catarrh may spread to the conjunctiva. The animal is not seriously ill, and the condition closely resembles that of acute nasal catarrh in the human subject.
>
> Immunity can be produced in the rabbit by the nasal route with vaccinia virus that has been attenuated by exposure to 55° C. for 30 minutes, provided that the dose is of the size found necessary in previous tests of this matter, employing the subcutaneous route. There is reason to believe that similar success may be obtained by the oral route if a large enough dose of the heated virus is given.
>
> When scarification is employed, the skin is more susceptible to the virus of vaccinia than is the nasal mucosa without trauma.

3. *Studies of the Virus of Variola.*

During the period that the investigation of the virus of vaccinia that have been described in preceding sections were in progress the occurrence of several outbreaks of small-pox in this country afforded an opportunity of testing examples of variola virus in a similar way to vaccinia. Dr. J. C. G. Ledingham has recently reviewed in these columns the experimental evidence in favour of the unity of the alastrim and variola virus (THE LANCET, 1925, i., 199). With his views Dr. Gordon appears to be in substantial agreement, and we pass therefore to record briefly the experiments recorded in the M.R.C.

report which bear on this important question. Dr. Gordon found that samples of variola virus obtained from cases of the mild and severe types of small-pox respectively had no effect on the rabbit, though they both affected the monkey when inoculated cutaneously. Vaccinia appeared to protect the monkey against either of these strains of variola virus better than the strains of variola protected that animal against vaccinia. It is particularly interesting to notice that specimens of variola virus from five outbreaks, including three of the mild and two of the severe type of small-pox, were all found to react positively with antivaccinia serum in the complement-fixation and agglutination tests. Dr. Gordon observes (p. 135)—

> As these laboratory reactions appear to be specific for the viruses of vaccinia and variola, there is good reason to believe that they are capable of affording valuable assistance in the practical diagnosis of small-pox, especially in doubtful cases where such help is most needed.

Thus no difference could be detected between the virus of the mild or alastrim type of small-pox and of the more severe type of this disease, except in regard to virulence for the monkey. The argument would have been even more conclusive had it been possible to employ cross tests of the capacity of virus from alastrim to protect a monkey against virus from severe cases of small-pox and vice versa. Nor has an antivariola serum yet been prepared by which the relation of various strains of variola virus to each other and to vaccinia respectively can be determined.

Before concluding our brief summary of this notable contribution to the literature of virus infections, which the laboratory worker will find stocked with valuable experimental detail, we wish to draw attention to three pages of the report which the general reader will find particularly interesting. In the section on the relationship between the viruses of alastrim, variola, and vaccinia (pp. 105–107) Dr. Gordon explains by the aid of a diagram his view that the vaccinia virus consists of equal parts of vaccinia and variola elements, and adds some striking quotations from the writings of Jenner and his biographer, which prove that Jenner himself had distinguished the two different manifestations of small-pox and yet realised their essential unity.

We propose to comment on certain other points raised by Dr. Gordon's work, particularly on the permeability of the nasal mucous membrane of the rabbit to vaccinia virus and the catarrh provoked.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 723.)

Society of Apothecaries of London.

(App. LXXXVI. and Q. 21218–21236.)

Evidence was given jointly on behalf of the Society of Apothecaries of London and of the Association of Certificated Dispensers by Dr. A. D. Brenchley and Dr. R. B. C. Wall, by Mr. Graham Bott and Mr. A. Wager.

By Section XVII. of the Apothecaries Act, 1815, it is not lawful for any person (except as in the Section mentioned) to act as an assistant—i.e., a dispenser—to an apothecary—i.e., a Licentiate of the Society—in compounding or dispensing medicine without obtaining the certificate of the Court of Examiners established by the Act. Dispensers who are holders of the certificate have been largely engaged by medical men or public institutions, and it was submitted that the nine months' training required by the Society's syllabus and the examination which candidates for the dispensers' certificate have to pass fully guarantee their fitness to dispense medicines.

The witnesses contended that the position of these dispensers had been prejudicially affected under the National Health Insurance Acts, and urged that holders of the certificate who had three years' practical experience should be recognised under those Acts for all purposes of dispensing supply of medicines. Although such a claim to recognition was adversely reported on by a Departmental Committee in 1913, the witnesses pointed out that the period of training had been raised from six to nine months, and further, that they proposed three years' practical experience in dispensing as a qualification. No claim was made that these dispensers should be allowed to keep chemists' shops.

East of Scotland Dentists' Panel.

(App. LXXVII. and Q. 19900–20114.)

This evidence, which was given by Mr. A. E. Miller and Mr. W. Arbuckle, followed in all essential respects that given by the dental surgeons in England. The recommendations put forward included one as to the necessity for a wide extension of dental treatment, and for its establishment as a permanent benefit, and the need for a separate administration in Scotland. Statements were made as to the dangers of dental disease, the insufficiency of the present "additional benefits," and the advantages of the panel system over a system of clinics.

The witnesses were asked how long it would take before the suggested saving in the cost of medical benefit brought about by a national scheme of dentistry would be reflected in the acceptance by the doctors of a lower capitation fee. The answer was that they were not interested in the question. On the question of a check against over-attendance, the witnesses did not think that the dentists were prepared to accept a scaling down of their bills.

> Suppose in respect of a simple filling, which is 5*s.*, at the end of the year, there was not enough money to pay all your bills, and instead of getting 5*s.* you only got a dividend of 4*s.*, what then ?—I did not think this was to be a sort of gamble.

Evidence of the Association of Poor-law Unions.

(App. XC. and Q. 21632–21725.)

It was submitted by Mr. R. A. Leach on behalf of the Association : That boards of guardians should be treated equally with other local authorities in respect of grants made from the National Exchequer for health work ; that other local authorities should not only be under no disability from entering into agreement with boards of guardians for the performance of any health work which the boards are doing for non-insured classes, but that encouragement should be given in every way to such agreements being entered into ; that in the case of an insured person who has no dependants entering the Poor-law institution for medical treatment the guardians be legally empowered to enforce payment to them by the Approved Society of any benefit payable in respect of the insured person during the period of his or her stay in the institution.

It was contended that the Poor-law medical service, both domiciliary and institutional, was excellent. As regards salaried officers remaining with the guardians, it was explained that while the younger men might hold short-time engagements in the same way as house surgeons in a general hospital, the principal medical officers tended to remain in the permanent service of the guardians. While the National Insurance Scheme had effected a lightening of domiciliary medical relief under the Poor-law, there had been a considerable increase on the institutional side.

As to possible changes in local health services :—

> Your contention is that if medical treatment was put under some new local health service, it would not alter the fact that it was Poor-law treatment under another name. That is your point of view, is it not ?—That is so, and I think myself it would be a great pity that the functions as regards the destitute poor should be entrusted to any authority which has duties other than dealing with public assistance.

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus : "App. X. 69," and references to the oral evidence thus—Q. 1369.

Association of Parish Councils of Scotland.

(App. LXXX. and Q. 20535–20636.)

Mr. M. A. Reynard, clerk to the Glasgow Parish Council, gave evidence to the effect that under the National Health Insurance Acts, as at present constituted, it is provided that no portion of the benefits payable under the Insurance Acts are to be allocated to boards of guardians or parish councils, where the insured person has been treated in a hospital belonging to such parish council. It was felt that not only is there an injustice in thus debarring parish councils from receiving payment from these persons for the treatment afforded, but also that, in many cases, the money is not put to a proper use.

The witness said that there was greater readiness nowadays on the part of the doctor and patient to accept Poor-law institutional relief, and yet that with 2256 cases of insured persons who were treated in hospitals by the Glasgow Parish Council last year, only £112 was voluntarily surrendered by the insured persons for treatment, as against an estimated expenditure of £12,000.

It was especially urged that where an insured person died in hospital and had no dependants any accrued sickness benefit should be paid over to the public authority. It was suggested to the witness that the Poor-law authorities had an already existing obligation to persons who were destitute, and that if insurance benefit were paid to an institution the effect would be that contributions by the State and by the employer would be used for the relief of rates.

As to the misuse of the funds by the patient, the witness cited a recent case of a patient who had just gone out of hospital and was squandering his sickness benefit money.

> He was entitled to his National Insurance money from December of last year up to date, and he frankly admitted to me that he had borrowed £3 on the strength of the £20 he was going to get, and he got drunk on it, and he came in demanding a certificate to go to his society and uplift the £20. I said to him, "What are you going to do?" He said, "It will keep me fine for a month anyway, and I will be back on you then."—And that is not an isolated case?—No, there are hundreds more of them. It is because of that that I am asking you to devise some method whereby we will get rid of that terrible waste of public money.

Evidence of Mr. W. J. Braithwaite.

(App. XCI. and Q. 21726–21827.)

Mr. Braithwaite, who was at one time secretary to the Joint Committee of National Health Insurance, confined his evidence to a recommendation that the system of payment per case instead of the capitation system—at any rate, for industrial areas—wanted more consideration by doctors and others than appeared to have been given to it.

The case system, he said, which involves the payment for each case treated, removed the suspicion that a doctor might not be glad to see an insured person, made it possible to introduce specialised services into the insurance system, gave the doctors at least the same interest in the quick recovery of their patients as did the capitation system, and resulted generally in a close approximation to the conditions of private practice.

Mr. Braithwaite said that the difficulty about chronic cases could be obviated by defining the period of an illness which would constitute a "case." Speaking from his recollections of the working of this system in Germany in 1910, the witness said that machinery would, of course, be necessary to guard against the possibility of "cases" being unduly multiplied.

It was suggested in the course of examination that if there was any tendency to multiply cases the psychological advantages of the system might be severely discounted by the friction and suspicion which might be engendered by the machinery of a check. The witness appeared to think that any attempt on the part of one doctor in a district to increase "cases," with the result that the remuneration of the other doctors was cut down, might fairly be left to the doctors themselves to provide adequate safeguards, as with the Manchester attendance system at present.

THE LONDON MEDICAL EXHIBITION.

The Medical Exhibition, which has just been held at the Central Hall, Westminster, proved, as we indicated last week, a decided success both from the point of view of the number of medical visitors and the scope of the exhibits; and the fact that a similar exhibition will be opened in the Philharmonic Hall, Liverpool, on Nov. 24th next for four days shows how much these exhibitions are appreciated. Among the reasons for this are the opportunity which is thus given to the medical man for making himself familiar with the more recent technique while affording him a means of selecting particular drugs and appliances which he may find useful in his daily practice.

While it is impossible to make any exact classification of the exhibits owing to their wide scope and the overlapping among the exhibitors of medical and surgical exhibits, we make the following broad divisions: Drugs and Foods, including Milk and its Preparations; Instruments and Appliances; Spas and Waters; and Medical Publishers.

Drugs and Foods.

Allen and Hanburys. Ltd. (37, Lombard-street, London, E.C., Vere-street and Wigmore-street, W.). in addition to their standard dietetic and pharmaceutical preparations, drew particular attention to Iodolysin, a soluble compound of thiosinamin containing 47 per cent. of iodine, which in many hands has proved so useful in rheumatism and allied conditions, and to sodium tetrabromphenolphthalein, for the X ray diagnosis of diseases of the gall-bladder.[1] Other notable exhibits of this firm were "Osmo" Kaolin for intestinal infections, the Lister Institute products—sera, vaccines, &c.—and Antivirus for use as a specific immuniser and bactericide in the treatment of local infections.—The exhibit of Burroughs Wellcome and Co. (Snow Hill Buildings, E.C.) provided a striking example of progress in scientific pharmacy. Amongst the more recent additions was "Hypoloid" Bismuth Metal, which places the potent spirillicidal properties of bismuth in isotonic glucose solution at the disposal of the physician; and "Kharsulphan," for subcutaneous or intramuscular injection, which provides a further simplification of arsenobenzol therapy; and "Iodicin," a product containing a high percentage of iodine in organic combination, in a pleasant, palatable chocolate base, is a very suitable means of administering iodine to children. Intensive iodine treatment is also facilitated by tabloid "Iodicin" capsules, each of which secures the administration of one grain of iodine in organic combination. "Ethidol," which contains 20 per cent. of iodine, is an allied product for use by injection into tuberculous abscess cavities, or for inunction in neuritis, rheumatoid arthritis, and sciatica. Vaccines, sera, tuberculins, and diagnostic products, prepared at the Wellcome Physiological Research Laboratories, were also displayed.—Boots Pure Drug Company, Ltd. (Nottingham), had an exceedingly fine display of synthetic and medicinal chemicals, solution tablets specially made to facilitate the rapid solution of drugs, demulcent and medicated pastilles, and dressings and surgical sundries. Among antivenereal preparations were Stabilarsan, Bismostab, Thiostab, and Acriflavine, while insulin and pituitary extracts were prominently displayed.—The Anglo-French Drug Co., Ltd. (238a, Gray's Inn-road, W.C.), showed a wide selection of pharmaceutical preparations, those receiving particular attention being Adrepatine, a pluriglandular compound for the treatment of hæmorrhoids; Creosal Syrup, combining guaiacol, phosphoric acid, and calcium, for the relief of cough; Digibaine, an association of digitalin and strophanthin; Iodaseptine, an intravenous bactericide; and Orargol, a suspension of colloid silver and gold. Labat syringes and needles were also shown.—Burgoyne. Burbidges and Co., Ltd. (East Ham, E.), displayed Cooper's Colloids in comprehensive range, including argentum, arsenium, ironmalt, hydrargyrum, manganese, iodum, and sulphur, the latter being for bath medication and for internal administration.—Bengué and Co. (52, Charlotte-street, W.), in addition to their well-known Ethyl Chloride, showed various pharmaceutical preparations, including Eupurgo for chronic constipation and hæmorrhoidal conditions; Muthanol, radio-active bismuth hydroxide suspended in olive oil, for use as a non-toxic spirillicide; and Forxol, a preparation of nucleogenic vitamins, for neurasthenia and diseases of nervous origin.

Oxo, Ltd. (Thames House, Queen-street Place, E.C.). In addition to the well-known products of this firm, Oxo, Oxo cubes, Hospital Oxo, beef essence, and Lemco, much interest was shown in their various "Oxoid" gland extracts, tablets, and fluid. Among them Pitoxylin, which is a new "Oxoid" endocrine preparation specially suitable for obstetrical, surgical, and general use, and consists of a sterile solution of the purified oxytocic and pressor substances from the posterior lobe of the pituitary gland. It is protein-free, and the undesirable ingredients have been eliminated so that the risk of inducing anaphylactic troubles when using the preparation is entirely avoided. Each batch manufactured is adjusted to a definite standard of activity.—G. W. Carnrick Co. (London agents: Brooks and Warburton, 40, Lexington-street, W.). Single gland and pluriglandular substances of many kinds were shown at this stand, where a 253-page book, "Organotherapy in General Practice," was at the disposal of medical men. Among the preparations to which attention was particularly drawn were Hormotone and Trypsogen.—Virol, Ltd. (Hanger-lane, Ealing, W.), in addition to Virol and Virolax, demonstrated the nutritive properties of Virol and Milk for nervous and mental fatigue after fevers and in convalescence generally, a golden-coloured powder which requires only the addition of hot water, and has been found of great use by nursing mothers.—Bovril, Ltd. (148–166, Old-street, E.C.), exhibited Bovril and Invalid Bovril, and Bovril and milk; and Vitmar, Ltd. (Callard's Vitamin Foods) (Standen-road, Southfields, S.W.), showed several forms of their food products.—Chas. Zimmermann and Co., Ltd. (9 and 10, St. Mary-at-Hill, E.C.), drew attention to Asthmolysin, a suprarenal-pituitary compound for relief in asthma, especially if due to hormone deficiency; Idozan, a therapeutic agent used in anæmia; and Posterisan, in the form of ointment and suppositories, a new vaccine therapy for local application in the treatment of hæmorrhoids and allied conditions.—The chief features of the exhibit by Oppenheimer Son and Co., Ltd. (179, Queen Victoria-street, E.C.), were Roboleine, now well known as a reconstructive food containing animal fats, maltose, diastase, and natural nitrogenous and phosphoric compounds with the three vitamins; Colloidal and organotherapeutic preparations, and the admirably adapted method of administering these last two by "Oscols" and Palatinoids. Particular attention was called by this firm to their automatic oxygen generator which is portable and safe and renders oxygen instantly available for medical use.—Parke, Davis and Co. (50, Beak-street, Regent-street, W.) had quite an interesting and attractive display of pharmaceutical preparations, among them being Dibromin, a practically non-toxic germicide used in dilute solution as a wet dressing, douche, or gargle; Metagen, a concentrated vegetable extract containing water-soluble and fat-soluble vitamins; and Metagen and cod-liver oil emulsion; Olgar, containing liquid paraffin of high viscosity with agar; and Neo-Protosil, a readily soluble colloidal silver iodide compound. This firm also showed vaccines prepared under the direction of Sir Almroth Wright at St. Mary's Hospital.—Lionel Cooper (14, Henrietta-street, Covent Garden, W.C.) had an interesting exhibit, and particularly noticeable among the many medical preparations was Milesia, a tablet containing 3 gr. of magnesium hydrate, Presoiod, an iodine solution, and Sil-Al, a physiologically pure silicate of aluminium.—C. H. Hewlett and Son, Ltd. (35–42, Charlotte-street, and 83–85, Curtain-road, E.C.), exhibited a selection of their antiseptic cream, medicated skin lotions, formalin mouth wash (Gargar); Hæmorrhaline, an improved ointment for hæmorrhoids; and Hormonigen, a combination of pluriglandular extracts; as well as surgical instruments, dressings, and sprays.—Howards and Sons, Ltd. (Ilford, E.), who supplies ether for anæsthetic purposes to many well-known hospitals, made a prominent feature of their Hydrogen Peroxide and of their Agotan brand of Phenylcinchoninic Acid as a remedy for rheumatism, gout, rheumatoid arthritis, brachial neuritis, neuralgia, sciatica, and gouty skin diseases.—Menley and James, Ltd. (64, Hatton Garden, E.C.), showed Iodex, a therapeutically active iodine in an emollient base, which does not stain or irritate the skin and is quickly absorbed.—W. Martindale (10, New Cavendish-street, W.), who displayed a large assortment of drugs and medical preparations, put up in attractive forms, drew attention to their absorbent moss surgical dressing; Aspriodine, a new compound of aspirin and iodine, as the name implies; and Phenoltetrabromphthalein, Tetraiodophthalein, and Tetrachlorphthalein for gall-bladder visualisation and liver function tests. This is referred to in the "Extra Pharmacopœia" of Martindale and Westcott, Vol. II., 1925.—H. R. Napp, Ltd. (3 and 4, Clement's Inn, W.C.), attracted much attention by their demonstration of rats showing the growth of carcinoma produced by the injection of tumour pulp and by the display of wax models showing the treatment of tuberculosis and allied mixed infections by cutaneous inoculation. Among the preparations shown were Ponndorf, for cutaneous inoculation in tuberculosis; Xifal Milk, a combination of sterilised milk; a vaccine for injection in epilepsy, myocarditis, and infantile paralysis; and Hypertherman, an injection for the protein body therapy of obesity. Vaccines and sera were shown in variety.—Hoffmann-La Roche Chemical Works, Ltd. (7 and 8, Idol-lane, E.C.) Allonal, which was prominently displayed at this stand, was reported upon in The Lancet as recently as Oct. 3rd, p. 706, as well as chocolate Iodostarin for the prophylaxis and treatment of simple goitre. Sedobrol Sedative Bouillon was also shown. This consists of sodium bromide incorporated in a mass of vegetable extractives put up in tablets. It is prepared by dissolving one or two tablets in a cup of boiling water. It is non-poisonous and non-narcotic.—May and Baker, Ltd. (Battersea, S.W.), showed a very fine range of drugs and chemicals, especial prominence being given to anti-venereal remedies, including Novarsenobillon, which has been approved by the Ministry of Health for use under the Venereal Diseases Regulations. This remedy has also been used in yaws, malaria, and rat-bite fever. Ametox, a purified and sterilised sodium thiosulphate for use as an antidote to metallic intoxication, especially in arsenical dermatitis and bismuth and mercury stomatitis, was shown among other drugs, as well as Mestarine, the sodium salt of theobromine N-acetic acid, which is a new addition to diuretic medication possessing stability and ready solubility.—Schering, Ltd. (3, Lloyd's-avenue, E.C.), prominently displayed samples of the medicinal products from their laboratories; Atophan, phenylchinolin carboxylic acid, for all diseases associated with uric acid diathesis; Atophanyl, a solution of sodium salts of atophan and acid acetyl sal. with 0·16 per cent. of novocaine, for injection in the treatment of laryngeal catarrh and other affections; and Maturin (the original product phloridzin), a preparation which produces artificial glycosuria in early pregnancy for the diagnosis of which it is employed.—W. Dederich, Ltd. (Stanley House, Dean Stanley-street, Westminster, S.W.), drew attention to Ichthyol, a sulphonated schist oil preparation containing a high percentage of sulphidic sulphurs. Other preparations shown by this firm were Ichthargan and Ichthoform, the former containing 30 per cent. of silver, the latter being an ichthyol-formaldehyde preparation. Mergal, a mercurial compound for the treatment of syphilis by oral medication, also received prominence.

---

[1] The Lancet, July 11th, 1925, p. 68.

Angier Chemical Company, Ltd. (86, Clerkenwell-road, E.C.), displayed Angier Emulsion (petroleum and hypophosphites), each fluid ounce of which contains 33⅓ per cent. of purified petroleum, 9 gr. of combined hypophosphites of lime and soda, with chemically pure glycerine.—Crookes Laboratories (22, Chenies-street, W.C.), devoted entirely to the manufacture of colloids, showed a wide range of these products, and with regard to Collosol Ichthyol claim with pride that it is a natural ichthyol of entirely British origin.—Anglo-American Oil Co., Ltd. (Albert-street, Camden Town, N.W.), exhibited their well-known Nujol and Mistol, and in addition, other preparations of liquid paraffin, including Semprolia, a petroleum jelly in both yellow and white colour, which can be conveniently used as an ointment base, and Semprolax, a palatable preparation containing 80 per cent. of liquid paraffin.—Dimol Laboratories, Ltd. (40, Ludgate-hill, E.C.), showed their product Dimol, a benzene derivative, dimethylomethoxyphenol in combination with the tri- and tetramethylopheno, is a bactericide which is claimed to be 35 times more efficient than pure phenol; it is not absorbed and is voided with the fæces. Indicated in putrefactive and other bacterial invasions of the intestinal tract, it is put up in the form of pulverettes, syrup, pastilles, lavage powder, ointment, snuff, and as a dentifrice.—Deshell Laboratories, Ltd. (Premier House, 150, Southampton-row, W.C.), exhibited Petrolagar, an emulsion of liquid paraffin and agar-agar, which is supplied (plain, alkaline, phenolphthalein, and unsweetened). It contains 65 per cent. of pure mineral oil of high viscosity and 10 per cent. of agar-agar.—British Alkaloids Co. (104, Winchester House) displayed antiseptics and germicides.

A large number of illustrated pamphlets showing the many uses of Antiphlogistine in medical and surgical practice and in dentistry were displayed by the Denver Chemical Manufacturing Co. (London, E.), and their product, the well-known antiseptic poultice which is indicated in inflammatory and congestive conditions, received much attention.—Genatosan, Ltd. (Loughborough, Leicestershire), in addition to Sanatogen, Genasprin, and Formamint, exhibited a new detoxicated vaccine prepared from *B. pneumosintes* for the treatment and prophylaxis of influenza.—Kolynos (Incorporated) (Chenies-street Laboratories, W.C.) showed their well-known non-gritty dental cream, which does not stain the teeth and is very refreshing and pleasant to use as well as being a reliable antiseptic, and the Pepsodent Co. (42, Southwark Bridge-road, S.E.) their equally well-known acid dentifrice, which stimulates the salivary glands and gives a brilliant polish to the teeth. It contains no injurious ingredients.—Jeyes' Sanitary Compounds Co., Ltd. (64, Cannon-street, E.C.), had a display of Cyllin in its many adaptations as a bactericide, whose slight toxicity makes it suitable for employment as an internal or external antiseptic. For medical and surgical uses the preparation has a Rideal-Walker co-efficient for *B. typhosus*, 24 to 26.—Newton Chambers and Co., Ltd. (331, Gray's Inn-road, W.C.), exhibited the Izal disinfectant specialties: Thermogene Co., Ltd. (Haywards Heath, Sussex, and Victoria Embankment, E.C.), showed their curative wadding, Thermogene, which stimulates the circulation in affected parts and relieves congestion and inflammation: J. C. Eno, Ltd. (Pomeroy-street, S.E., and Victoria Embankment, E.C.), drew attention to their effervescent saline laxative, Eno's Fruit Salt; and Keen Robinson and Co., Ltd. (incorporated with J. and J. Colman) (London and Norwich), showed various preparations of barley and mustard.—The City SoapWorks (Wapping, E.) exhibited Gibbs's various soaps, shaving creams, and dental cream; the Pinoleum Co., Inc. (Distributing agents, Brooks and Warburton, 40/42, Lexington-street, W.), demonstrated the use of Renoleum, an anodyne, antiseptic, and emollient preparation for medication of the mucous membrane of the throat and nose; Pastilles, Ltd. (124, High-street, Shoreditch), had a display of Lakerol Bronchial Pastilles; and Irving's Yeast-Vite Laboratories (Cecil House, Holborn Viaduct, E.C.) showed yeast tablets.

Jaeger Co., Ltd. (95, Milton-street, E.C.), displayed their well-known wool underwear. Endocrines, Ltd. (distributors for the Harrower Laboratory, 72, Wigmore-street, W.), exhibited pluriglandular preparations under the name of Polycrines. There were over 30 combinations of ductless glands in tablet form ("sanitablet"), every dose being enclosed in an airtight damp-proof envelope. Among new preparations are Sol. Placento-Luteum Co., for use in the vomiting of pregnancy, while attention was also particularly called to Adreno-Spermin Co. for neurasthenia; Pan Secretin Co., for diabetes; Thyro-Ovarian Co., for dysmenorrhœa; and Gonad Co. for rejuvenation. Many of the preparations are put up in ampoules for hypodermic injection. This firm presented free to medical men a 300-page book, "A Manual of Pluriglandular Therapy."—Organotherapeutical products were also shown in large variety by the British Organotherapy Co., Ltd. (22, Golden-square, Regent-street, W.). Among others noted were the Lymphoid Compound and Lymph Serum, pluriglandular preparations which have been used in nervous disorders resulting from the war and otherwise and in securing the rejuvenation of elderly people; extracts of the brain and spinal cord; Corpus Luteum Extract; Eukinase, prescribed in the treatment of intestinal indigestion and chronic constipation; Gastric Mucosa Extract, for gastric dyspepsia; Hepatic Extract, for liver torpor; and Lymphatic Gland Extract, for the treatment of adenoids without operation. The preparation Hæmatothyroidine was also shown. This is employed in the treatment of exophthalmic goitre, as well as Saccharomycin, an isothermal, isotonic, and living yeast specially prepared for medical use.—Armour and Co., Ltd. (Queen's House, Kingsway, W.C.). At this stall a large selection of Endocrines were shown in the form of desiccated powder, tablets, capsules, liquors, and hypodermic solutions. Digestive ferments of all kinds are manufactured in the Armour Laboratories in Chicago, as well as surgical catgut and such specialties as glycerine and extract of red bone-marrow.

The Garden City Pure Food Co., Ltd. (95, Westminster Bridge-road, S.E.). The Soya Double Cream, Soy-Yeast, Soya Biscuits, and Soya Flour exhibited by this firm are primarily intended for diabetics, and there is an entire absence of starch or sugar in their composition. The Double Cream and Soy-Yeast are in powder form and are easily converted into food drinks. By a special process the unpalatable flavour of Soya preparations has been greatly modified and the products should make a useful addition to diabetic diet.—Mead's Infant Diet Materials (Distributors, Brooks and Warburton, 40/42 Lexington-street, W.). The Dextri Maltose and other infant diet materials prepared by this firm are intended to be prescribed by a medical man, consequently no directions are printed on the containers. The foods include Mead's Casec, used in the preparation of protein milk for the treatment of fermentative diarrhœa; Mead's Powdered Protein Milk with lactic acid; Mead's Certified Cod-liver Oil; and a reconstructed milk powder, Re-co-lac, a breast-milk substitute.—Savory and Moore, Ltd. (143, New Bond-street, W.), prominently displayed their well-known food, which can be prepared to approximately resemble mothers' milk in composition, together with their peptonised milk preparations.—Therapeutic Foods Co. (Energen Works, Bridge-road, Willesden, N.W.) prominently exhibited their starch-reduced foods standardised for use in dietetic treatments with constant proportions of carbohydrate and protein. These consisted of bread, biscuits, and flours, as well as cocoa essence.—Prideaux's Pure Casein and Life Food Co., Ltd. (Southwark-street, S.E., and Motcombe, Dorsetshire), exhibited dried full cream milk prepared entirely from new milk under hygienic conditions.—Cow and Gate Milk Food (Cow and Gate House, Guildford, Surrey). The product of this firm is manufactured by the West Surrey Central Dairy Co., and is also made in Dorset and Somerset from the milk of prize herds. The process of manufacture eliminates all contamination, and it is claimed for the food that it produces in infants results identical with those of healthy breast milk.—Glaxo Dried Milk Products (56, Osnaburgh-street, N.W.) showed their various forms of dried milk, Glaxo Malted Food, Glax-Ovo, and their Diabetic Milk Food. Prescription (Humanised) Glaxo was also made a prominent feature of the exhibit; and Ostelin, a high concentration of the antirachitic unsaponifiable fraction of cod-liver oil, called forth many inquiries. The Maltine Manufacturing Company's products have now been taken over by this firm.—Hooker's Malted Milk (Thew Hooker and Gilby, Ltd., Buckingham). This well-known preparation, which is completely soluble in either hot or cold water, is quickly prepared, and is of use both in sickness and health. —Horlick's Malted Milk Co. (Slough, Bucks). This is also a well-known preparation which had a prominent display. — Trufood, Ltd., Creameries (Wrenbury, Cheshire; offices, Lever House, Blackfriars, E.C.), showed their Humanised Trufood, which closely approximates to breast milk; Trufood Full Cream for use from 9 months onwards, for nursing mothers and for invalids; and Secway, a pure, sweet whey powder which can be used as the basis of feeding in gastric disorders, even in the case of young infants.—S. Guiterman and Co., Ltd. (35/36, Aldermanbury, E.C.), exhibited Cereal Meal, a food whose object is to produce normal daily intestinal evacuation; Brusson Jeune and Co. (311, Gray's Inn-road, W.C.) Gluten breads and foods for diabetes, obesity, gout, indigestion, rheumatism, and invalid dietaries; A. C. Fincken and Co. (197, Great Portland-street, W.) H-O Quick Cooking Oats; and Sister Laura's Infant and Invalid Food Co., Ltd. (Springfield Works, Bishopbriggs, Glasgow), a food for infants and invalids.—Cadbury Bros., Ltd. (Bournville, Birmingham), supplied to visitors cups of their delicious beverage and a book of useful recipes for making chocolate cakes and sweets.

(*To be concluded.*)

BUCHAREST.

(From our own Correspondent.)

Reform of the Workmen's Compensation Act in Roumania.

The Minister of Public Welfare has delegated Dr. George Cimponariu, the director of the central "sick club," to find out how unification of the sick club system may be accomplished, as the States recently incorporated into Roumania—namely, Transilvania, Bessarabia, and Bukovina—have each a different system, though in Bessarabia the treatment of workmen, both from a social and from a medical point of view, is very primitive. The most perfect system is the Transilvanian (formerly instituted by Hungary), and on it the new scheme will be modelled. Dr. Cimponariu says that the most important task of the sick club will be not only to give temporary help to the patients, but also to exercise medical control over all industrial undertakings and factories, and thereby combat the industrial diseases. The protection of workmen against tuberculosis will also claim attention. Mothers will be granted a considerably greater support than prescribed by the law. Under the new scheme a working mother will be granted a holiday at the time of her confinements, commencing four to six weeks previous to the event and continuing for eight weeks thereafter. Infants will be under medical supervision up to a certain age. In the larger factories day homes will be established where working mothers can feed their babies. It is unfortunate that no satisfactory method has as yet been suggested for protection against venereal diseases, which claim victims among the working class. According to recent statistics, every workman loses, on an average, 26 working days in a year on account of venereal diseases. The Central Workmen's Insurance Offices have also planned the erection of sanatoriums, although the present low rate of exchange prevents building. For this reason contracts were made with various private sanatoriums for a certain number of beds.

The Teaching of Roentgenology.

The study of roentgenology has for some time been compulsory in every university in Roumania, although students were not obliged to pass an examination in it. Recently, however, examinations in that subject, both theoretical and practical, have been made obligatory. If a student fails he has to continue the subject for two seasons. Coincidently with this ruling, all university clinics have been furnished with X ray apparatus of the transformer type, both for diagnostic and therapeutic purposes, and also the application of " deep therapy."

Medical Certificates for Marriage.

After the introduction of many medico-social institutions, as, for example, the nationalisation of the medical treatment of workmen, the establishment of free venereal and tuberculosis clinics in every large town, the granting of State support to the victims of industrial accidents in cases where the employers have gone bankrupt, the Government sent out to various countries a commission to study the different methods of controlling the health of couples intending to marry. The commission recommends the method practised in certain of the States of North America. It proposes to forbid all matrimonial offices to wed couples unless they produce a medical certificate (from any physician they may choose), the certificate to be signed by a sanitary officer, who has the right to examine the parties if any doubt arises as to the validity of the certificate. The discussion of this question in the daily papers is prompting intelligent fathers to demand, before consenting to the marriage of their daughters, that the suitor produce medical evidence as to his general health and freedom from venereal disease.

The Price of Alcohol Raised.

The pharmaceutical papers of Roumania are lamenting the new regulations regarding the alcohol monopoly, which extend the general tax on alcohol to alcohol used medicinally, which has hitherto been exempt. The manufacturers of perfumes and cosmetics succeeded in getting the tax reduced for their use, in order to protect this industry, which lately, owing to the intensive culture of roses and the manufacturing of rose-oil, has grown by leaps and bounds. Pharmacists are allowed to use a cheaper alcohol for tinctures and fluid extracts, but only if the process of preparation is done under the supervision of an official. The regulations provide for new officials for this purpose, and a medical paper, the *Viata Medicala*, remarks that the number of pharmacists will dwindle as the result of this measure, and consequently the manufacture of tinctures, and so forth, will fall into the hands of the manufacturing chemists, as was the case in Germany, whence this new regulation was copied.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Men in the Senate of the Irish Free State.

THE final results of the election of 19 members of the Senate were announced last week. Two medical men are among the successful candidates. One of these, Mr. H. S. Barniville, was a previous member of the Senate, having been nominated one of the original Senate by President Cosgrave in 1922. He is one of the surgeons to the Mater Misericordiæ Hospital, Dublin. The other medical man who has been elected is Sir Edward Coey Bigger, formerly medical member of the Local Government Board for Ireland and chairman of the Irish Public Health Council. Sir Edward Bigger has always been an ardent influence in matters of health. He was one of the members of the Vice-Regal Committee on the Poor-laws which reported nearly 20 years ago, and in 1919 he was chosen as chairman of the Irish Public Health Council, which subsequently sent in a report recommending many drastic changes.

Royal Academy of Medicine in Ireland.

The annual elections at the Royal Academy of Medicine took place last week. Sir James Craig remains in office as President, and Dr. T. P. C. Kirkpatrick as general secretary and treasurer. The following, with representatives of the sections, constitute the General Council: Dr. A. F. Dixon, Sir J. W. Moore, Dr. T. G. Moorhead, Dr. G. E. Nesbitt, Dr. R. J. Rowlette, and Sir W. I. de C. Wheeler. The following Presidents of Sections have been elected: Medicine, Prof. F. C. Purser; Surgery, Mr. R. C. B. Maunsell, President R.C.S.I.; Obstetrics, Dr. D. G. Madill; Pathology, Prof. J. W. Bigger; Anatomy and Physiology, Dr. C. M. West; State Medicine, Prof. V. M. Synge.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs to be Surg. Comdrs.: G. S. Harvey, W. H. Murray, and G. H. Hayes.

ROYAL NAVAL VOLUNTEER RESERVE.

A. J. Gilbertson, late Surg. Lt.-Comdr., re-entered as Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj. T. W. Stallybrass retires on ret. pay.

Capt. F. K. Tomlinson retires, receiving a gratuity.

Capt. N. Cantlie is restd. to the estabt.

REGULAR ARMY RESERVE OF OFFICERS.

Col. R. J. Blackham, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ROYAL AIR FORCE.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: T. V. O'Brien and F. W. G. Smith.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers: Majs. H. W. Pierpoint, W. D. H. Stevenson, H. P. Cook, P. S. Mills, W. J. Fraser, C. A. Godson, R. H. Lee, F. P. Warwick, W. A. Mearns, and R. G. G. Croly to be Lt.-Cols.

Capts. G. H. Mahony, G. Covell, W. R. Stewart (Bt. Maj.), Venkatasubba Mahadevan, and A. C. L. O'S. Bilderbeck to be Majs.

Capt. H. J. Rice is confirmed in his rank.

Capt. Vasantrao Dinanath Madgaokar relinquishes his temporary commission.

In the Legislative Assembly at Simla on Sept. 2nd, in spite of Government opposition, a resolution was carried that all further recruitment to the Indian Medical Service shall henceforth be only by an open competitive examination held simultaneously in England and India from the year 1926.

Captain E. R. Daboo officiates as Civil Surgeon, Sadiya, Assam. The Executive Council of Lucknow University has elected Major H. Stott to represent the University on the Medical Council of the United Provinces of Agra and Oudh. Major T. T. H. Robinson, D.S.O., has been appointed Civil Medical Officer, Ranikhet, vice Lieut.-Colonel W. C. Croly, D.S.O. On return from leave, Dr. W. G. Wince and Dr. C. H. Mason have been re-posted as Civil Surgeons at Wardha. Captain P. Verdon has been appointed District Medical Officer at Guntur. Major B. Gale has been posted to Amballa. Dr. Kali Charan Dube has been appointed Medical Officer of Health at Meerut, vice Dr. Nand Lal Varma, who reverts to the Provincial Medical Service. Colonel H. O. R. Browne Mason officiates as D.D.M.S. Western Command, vice Major-General S. F. St. D. Green, who has proceeded on leave.

THE MOTOR SHOW AT OLYMPIA.

OCT. 9TH–17TH.

(BY OUR MOTORING CORRESPONDENT.)

THE nineteenth annual International Motor Car Exhibition, held by the Society of Motor Manufacturers and Traders, which closes to-day (Saturday) has fulfilled the expectations of everyone. The motor show has now been for a long time a national institution, and thousands, not only of the trade nor even of motor-car owners, but also of the vast car-less public, look forward to it eagerly, for all the cars they have recognised and coveted stand here in the glory of their show finish, open to be inspected and admired, opened and shut, sat in, and in imagination driven at great speed along straight black roads. Many makers have their engines sliced open, so that we can see for the first time exactly how sleeve valves or overhead camshafts work, and such anticipated wonders as the new six-cylinder Bentley, the "New Phantom" Rolls with six brakes, and the 25–70 sleeve-valve Vauxhall are at last realised.

A Retrospect.

The habitual visitor to Olympia always feels, the moment he enters the building, that he has come home. Except that it is half as large again, there is no apparent difference between the show to-day and the show of 1912. A few new names appear on the great white panels over the stands and the lights may be brighter and more numerous. The noise of the horns in the gallery is gone for ever. But the stands and the cars on them are neither larger nor more splendid than they were then, and unless one looks very closely neither machinery nor bodywork seems to have altered in anything but small detail. Actually, however, the change is vital. The doctor who wanted in 1912 to spend £200 on a car was tied down to about half a dozen makes, nearly all heavy and under-powered. There were no electric starters and electric lights, and none of those side-screens and screw-down hoods that make any open car waterproof in three minutes to-day. Most of the accessories were extras, and the tool outfit supplied with the car was heart-breaking. Next year came a rush of 10 h.p. two-seaters that, led by the far-sighted experiment of the Morris-Cowley, grew into eleven-nines after the gap made by the war, and then a year or two later into thirteens and fourteens, while a fresh crop of sevens, eights, and nines with incredibly powerful engines sprang up in their place.

There is no comparison at all between the Talbot or Gwynne 8, or the Austin or Jowett 7 of to-day and the A.C. and Singer 10 or the Morris-Oxford 9 of 1914, and the reason is the immense increase in knowledge that the war gave to the designer of all kinds of internal combustion engines, and in particular those of aeroplanes. A glance through a buyers' guide will show that power is now quoted in two figures—e.g., 8–18, 15–50, 20–60—the first being the taxable power and the second the horse-power the engine actually gives at its best speed. It is not an exaggeration to say that, size for size, engines are three times as powerful as they were before the war, and a glance at the Austin 7 or the Aston-Martin 11 shows that this improvement is not confined to engines with overhead valves, though more and more makers are fitting them.

1925.

The power-price of most cars is now back again approximately to what it was in 1914 and is not likely to go any lower, but it now includes a perfect lighting and starting set, an "all-weather" equipment that closes the car in almost as completely as a permanent top, a whole shop-full of accessories like mirrors, dashboard-lights, screen-wipers, luggage grids, clocks, air-stranglers, and safety-locks, and very often front-wheel brakes as well. The competition of the cheap American cars has provided the chief impulse to this development, but our manufacturers have responded to it in a way that does the country great credit. The Standard Motor Co. gave us the all-weather screening and Morris Motors took the lead in supplying the cheap car with all the accessories of the expensive one, especially one that is worth more than all the others put together, the system of greasing the whole chassis with one gun that fits on to special nipples.

Four-wheel brakes were fitted on the Argyll and the Isotta-Fraschini nearly 20 years ago, but only became popular about the beginning of last year—chiefly because of the way in which they contributed to the success of the Peugeots in the Grand Prix the year before. There is now hardly a car on which they cannot be fitted if required, and many have them as standard. They are excellent if they are properly adjusted, but apt to be highly dangerous if they are not. The front wheels must brake together, and most people prefer them to come on later than the back.

Returning to cars in general, however, we see that the 11·9 h.p. of 1½ litres, so general three years ago, is losing its hold on popular favour. There are now a great many twelves, such as the Morris-Oxford, Hampton and Bayliss Thomas, and fourteens and fifteens like the new Triumph, the Lagonda, and the Hillman, that are the descendants of former eleven-nines. The new 2½-litre car is very nearly the old family 15·9 that was so popular once, and it is most pleasant to see this convenient size reappearing. Five people could always be sure of finding in it ample room for their feet and a certain amount of luggage as well.

Two Examples of Modern Practice.

A very good example is the *Beardmore* 16–40 h.p. These manufacturers are well known for their excellent aircraft engines and their taxis, and the new 16–40 will not fail to increase their reputation. They make a saloon for £550 in which there is that rarest of things, a really comfortable driving seat with all the controls in reach on the right-hand side. The pedals are adjustable and a wheel-base of 10 ft. 6 in. gives ample leg room. All these cars have front wheel brakes and stand close comparison with the £1000 class in every way. There is no better value to be found in the whole show.

The *Triumph* 15–50 h.p. is a similar model, but a little smaller. Triumphs were the engineers who rescued the British motor-bicycle from extinction in the first decade of the century; a year or two ago they produced one of the finest small cars in the country, and have now passed on to a 2-litre chassis. It would be very hard to beat the open five-seater at £395 or the four-door saloon at £495 or £460, but it is a pity they only fit three gears. The front wheel brakes are hydraulic, and every conceivable gadget is fitted, including a very good tool kit.

Tool Kits.

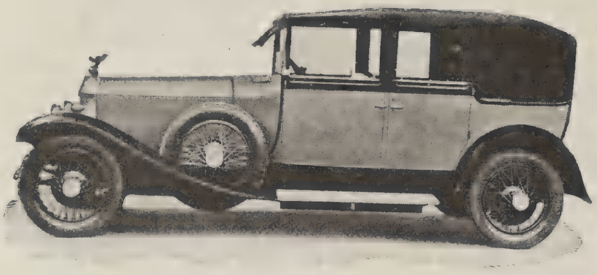
The result of a careful inspection of tool kits at the show was reassuring. Even the very cheap cars now carry a modest but perfectly adequate set, and the makers of the more expensive ones take care that their jacks and pumps shall be up to the standard of their cars, which they did not always do a few years back. Even so, there are very few who include a box of the spare nuts and small parts, the absence of which will sometimes keep a car in dock for a week. It was surprising, too, in how few cars a six-foot person could stretch his legs and at the same time reach gear- and brake-levers without leaning forward. Hand-brake levers are much longer and better placed than they were; the ones on the Lancia, Darracq, and Talbot pull upwards from the floor and give a tremendous leverage, but most of those on the right-hand side are far too near the coachwork. The A.C. has an excellent one, and nearly all the American cars are very good. One Italian car has a spade handle, and it is a pity more makers do not copy this, as it gives a natural grip, particularly to the left hand. On the whole, though, makers of small cars are inclined to omit the extra four inches which make all the difference, especially the Morris, where the hand-brake is the one blot on an otherwise beautiful control system.

Coachwork.

Body-work as a special industry remains at the same level of perfection.

Barker's Cabriolet de Ville has a folding roof that will cover all the seats or the back only as required, and will fold up completely in fine weather. As its protection when fully closed equals that of a saloon, it combines the advantages of all types of bodies. A splendid specimen of their work is on the large Rolls-Royce (Fig. 1) in blue and black, with upholstery in plain light cloth and a folding arm-rest.

Fig. 1.



Rolls Royce. Body by Barker.

Mann, Egerton and Co., Ltd., showed a 14–40 Vauxhall saloon and a 25–85 Daimler with their own four-door saloon body painted powder blue. An interesting exhibit was a 30 h.p. Minerva, enclosed drive limousine, the body staged in an unfinished state, from which could be judged the excellence of the coachwork before it was painted.

Offord and Sons, Ltd., exhibited among other cars a 14 h.p. Crossley saloon landaulette.

Windovers, Ltd., had fitted another of the Rolls exhibit, a 20 h.p. with a six-seater Brougham Limousine (Fig. 2) in black—a most handsome town car.

Belgravia Coachworks had a very attractive 3/4 Landaulette on a 14 h.p. Bean chassis and a saloon Limousine with six seats on a 17·9 h.p. Renault.

Coachbuilders are tending to make more use of the new scratchproof cellulose compositions and safety glass. Most of the bigger saloons have four doors, and windows are almost invariably raised and lowered by cranks or other mechanical devices. V-fronts are holding their own, and larger windows are fitted at the backs of closed cars, a most necessary modification, as anyone will know who has ever tried to reverse a large covered car into a narrow garage.

The Large Cars.

Undoubtedly the chief joy of Olympia for the ordinary person is to examine closely, and perhaps to sit in, the huge expensive cars that he covets on the road but never hopes (and if he is wise never really desires) to possess. *Rolls-Royce* had their "New Phantom" with the improved engine and the six brakes system, *Daimlers* had their 35/120 sleeve valve, but the most interesting of all was the new *Bentley.*

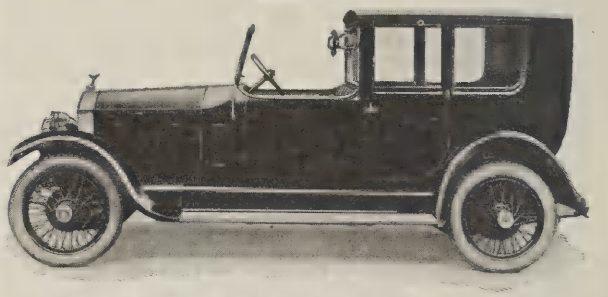
Bentleys are the only manufacturers that have ever stepped straight into the first rank with a new car, and since 1922 their name has become as familiar as that of Rolls-Royce. The car was the famous 3-litre 17·9 h.p. with 16 overhead valves, which would do 75 miles per hour with a saloon body and was incomparably finer than anything of its size in existence. They have now surpassed themselves with a new six-cylinder machine (Fig. 3) of 6½ litres, with 24 overhead valves, taxed as 38 h.p., but developing well over 100, which, if it maintains the standard of the earlier model, will be unique, as the life of the small Bentley is almost endless, and it is designed to need no attention. The most interesting feature of the big one is the camshaft drive, which consists not of gear wheels, but of two triple crankshafts connected by three pairs of stout tubes, which work in a large conical tunnel behind the engine. To counteract expansion was the chief problem, and it was solved by fitting spring bearings to the connecting rods at each end. The engine is mounted in front on a fabric pad and behind on two blocks of rubber, which insulate it from the frame; a new clutch design is fitted and the steering gear is redesigned to allow for the extra resistance of low-pressure tyres. It is a marvellous car.

Another of the most attractive large cars is the eight-cylinder Packard from America, a straight eight with the generator, starter, and carburetter all standing out from the clean run of the cylinder casting and extremely accessible. The engine, which is very long, is in the neighbourhood of 40 h.p. by our rating. Flint, Chandler, and Kissell are other large cars that represent the best of the American market.

Cars for the General Practitioner.

Now that makers are going in so much more for closed bodies, and that all cars are so reliable and easy to look after, the medical visitor will find that 85 per cent. of the cars shown would suit him perfectly. Even if he can only afford a maximum of £200 he can choose between a good dozen examples, such as Morris-Cowley, Jowett, Baby Austin, Briton, Citroën, Clyno, Peugeot, Chevrolet, and Trojan, and if he has £500 he can take his pick of half the show.

Fig. 2.

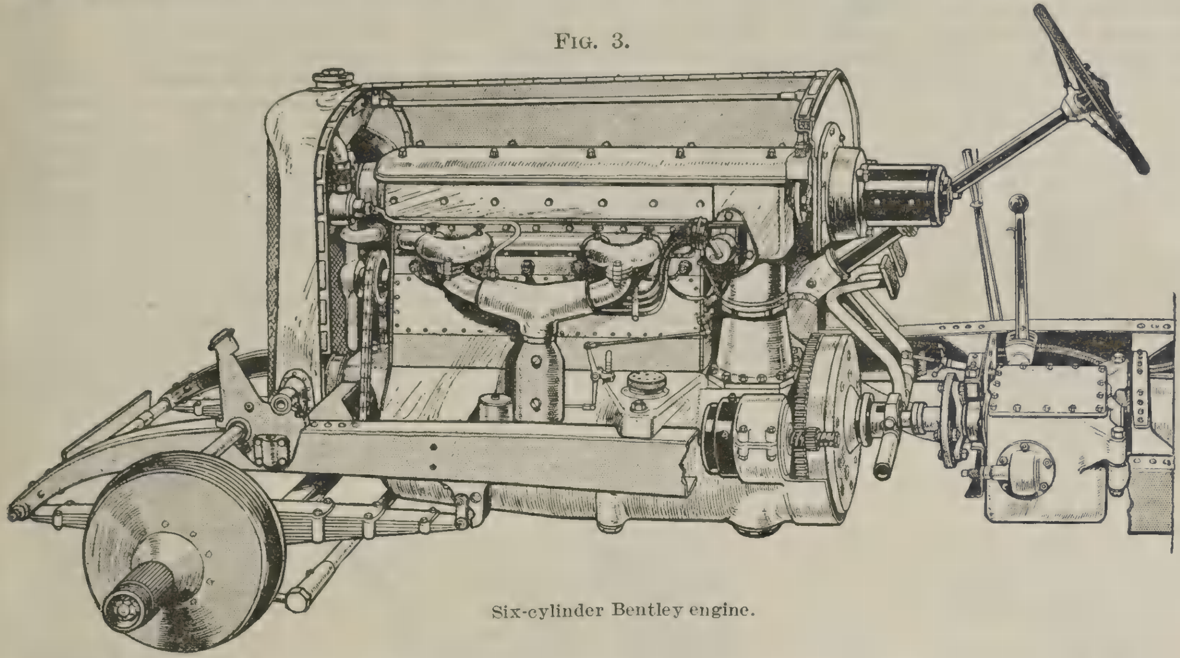


Six-seater Brougham Limousine by Windovers, Ltd.

Of orthodox two-seaters and saloons there is no end, and quite a number of makers still include the coupé in their standard range, but this wide two-seated body with its high bulwarks and solid folding top and carriage-windows, so suitable for the doctor who drives on winter nights, is showing signs of diminishing popularity. It is probably being ousted by the small saloon. There is one beautiful two-seater of a rather "sporting" type, however, with a semi-coupé top, that would be just the thing for a practitioner who wanted a car rather faster than usual but still suitable for everyday (and every night) practice. This is the *B.S.A.* 16 h.p. six-cylinder sports two-seater (Fig. 4). The body is cream-white, with red wings and mouldings, and the hood folds down and clamps to the raked wind-screen. There is ample room under the "quarter-deck" for spares and luggage and one passenger in the dickey. The engine is the 16 h.p. sleeve-valve Knight-Daimler, which is practically inaudible and extremely powerful. The car should do 65 miles per hour easily. Other bodies on this chassis are the open five-seater at £550 and two saloons at £550 and £600. It is really a cheaper Daimler, and so is extremely good.

Another of these small six-cylinder cars is the *A.C.* 16/40 h.p. This car is unique in that it has a 2-litre engine in a chassis only 2 cwt. heavier than their 4 cyl. 12 h.p., and so is exceptionally lively. One model that looked pre-eminently suited for a doctor is called the "Aceca" (Fig. 5) and costs £560. A disadvantage of the ordinary coupé is that it is very hard to see out of, and the Aceca body with the hood down is just like an ordinary very comfortable two-seater. The wind-screen is raked, however, with two triangular side-pieces, and the driver can pull the hood over and lock it to the top of the screen with the car on the move. When the windows in the doors are pulled up the protection is that of a coupé. This ingenious body is also fitted to the four-cylinder chassis at £495. There is a great variety of bodies to choose from between the cheapest A.C. at £300 and the racing four-seater at £800.

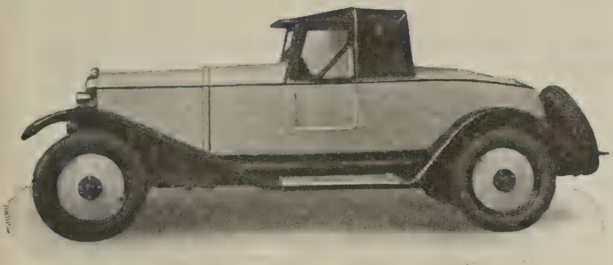
FIG. 3.



Six-cylinder Bentley engine.

The *Lancia* " Lambda " is the only foreign car for which there is no British equivalent. It is daringly unorthodox, being built very low down on a pressed steel frame with body and chassis in one piece, like a destroyer. The naval reminiscence is helped by the casing of the driving-shaft that runs the whole length of the seating-space, and in fact by all the low straight lines of the car, the lift of the scuttle, and her great liveliness. There are several improvements since last year. There are now four speeds, and the wheelbase has been lengthened on one chassis from 10 ft. 2 in. to 11 ft. 2⅝ in. The low seats are amazingly comfortable and the controls are exactly right. The makers claim 70 miles per hour for it. The shorter saloon costs £725 and the longer, with two extra folding seats, £800. Both saloons have a top which will come off and leave the car open for the summer. There are double Hartford shock absorbers on the back springs; in front are the Lancia vertical springs that contain their own dampers. The car is exceptionally light on fuel and tyres.

FIG. 4.



16 h.p. B.S.A. Sports two-seater.

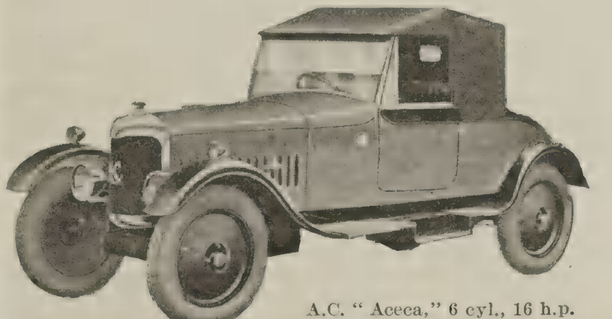
In the less ambitious class there are so many possibles that we are reduced to an invidious choice. One or two stand out slightly from the rest, and among them is the *Hampton* 12 h.p. coupé at £330, four-wheel brakes £345. It has a wide double dickey, a single-handed hood, and patent window lifts; the driving position and hand-brake lever are really comfortable. Screw-down bonnet clips of the kind that the Citroëns introduced into the country are a sign of the careful designer, and the dashboard has the now almost universal " cubby-hole " which was first started by the Standard makers.

A Scotch car that has fully proved its worth is the *Galloway* 12. The firm is a daughter of Arrol-Johnstone's, and fully sustains the parent's reputation. The engine has overhead valves of a new design that makes it exceptionally silent, and unlike most overhead valve engines it does not become noisy with use, which can be said of very few others. Four speeds are fitted, with right-hand change, and the speed and brake levers are well apart. Four-wheel brakes are £10 extra; the two-seater is £265 and the saloon £360.

The *Windsor* 10–15 coupé, by James Bartle and Co., Ltd., at £465, is another first-class car for the doctor. It has ample locker and luggage accommodation, a leather hood, and four-wheel brakes.

The *Essex* coach at £295 is remarkable value.

FIG. 5.



A.C. " Aceca," 6 cyl., 16 h.p.

Wolseley Motors, Ltd., have confined themselves this year to three models, an 11/22, a 16/35, and a 24/55. The small car is even better than the famous 10, but we miss the 14, which covered itself with glory in Major Forbes-Leith's drive to India. The 11/22 two-seater costs £235, with four-wheel brakes extra.

Low-priced Cars.

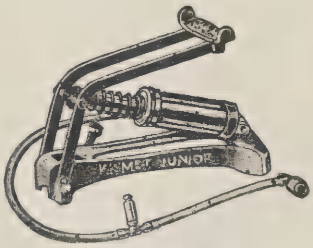
For the many who want a reliable car to get about in at the lowest possible price, Olympia caters better this year than it ever has before.

The Leyland *Trojan* 10 h.p. is very well known now, with its clean simple lines and its solid tyres and chain drive. The springing is literally better than that of any other car on the road, and the two-stroke engine very economical. The ordinary model at £125 represents the cheapest motoring there is, but the firm also sell a coupé with a detachable top, fitted with pneumatic tyres, at £158, that the country practitioner would find an ideal means of transport. There are no sliding gears, which will appeal to the beginner.

The *Peugeot* 7·12 is a remarkable little French car with a great name. The two-seater costs £150 and the smart weatherproof cabriolet £185. The makers have been daring enough to revert to the straight-through gear-change, which many drivers prefer to the gate. The car can be thoroughly recommended.

The *Morris-Cowley* 11·9 at £162 10*s.* has Gabriel shock-dampers, spring gaiters, a grease-gun system, electric lighting and starting, a dashboard light, and a radiator thermometer, and for £180 front-wheel brakes. It is unquestionably the best-equipped car of its price on the road, and is certainly one of the sweetest to drive. Its only disadvantages are that its brakes are nearly always noisy and the hand-brake lever is too short. The Morris-Oxfords are rather larger, and are very fine cars indeed; they cost from £90 to £130 more.

FIG. 6.



The Kismet patent foot pump.

ACCESSORIES.

A tour of the galleries this year, though very instructive, showed hardly anything new, but that is largely because everything that a motor-owner could conceivably require, and plenty that he could not, is already obtainable. The owner-driver is not as a rule very interested in paint, preferring to leave such a difficult subject to the coachbuilder, but *Robbialac* is always a standby to him, as it requires very little knowledge to apply and dries quickly and well. It is a most useful enamel for covering up odd scratches and dents in mudguards. The *Carmaloid* firm exhibited their now well-known celluloid enamel, which is being increasingly used by the makers of bodies. It is non-inflammable when dry and very elastic and tough; its polish improves with wear. It has also the great advantage of drying in a single hour at 70° F.

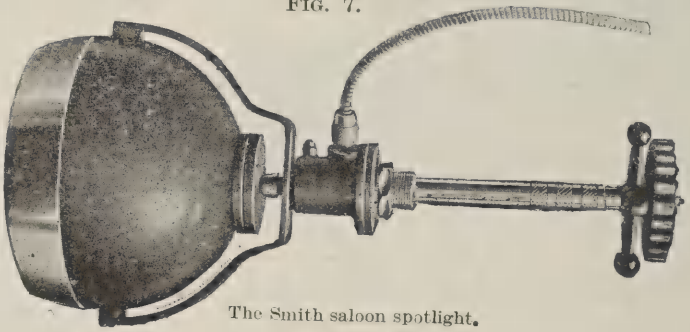
Tyres, Jacks, Pumps, Shock-absorbers.

The "balloon" tyre increases in popularity, which is not surprising, for it enormously adds to the comfort of any car, besides improving its appearance. Most tyre makers now market a full range of low-pressure and medium-pressure tyres, especially *Dunlop* and *Michelin*, whose products are better and more widely used than ever. The owner of a car with these tyres, however, must be very careful indeed to keep his pressure up to the figure recommended by the maker, since if they are under-inflated they are liable to roll off the rims when taking a bend at speed, which may cause a very serious accident. He can completely insure himself against mishaps of this kind for 6*s.* 10*d.*, and a little care, by purchasing the Schrader gauge. It is a small nickel tube about the size of the little finger, which with its adaptor will fit any valve. When it is pressed against the opening a black graduated plunger shoots out from which the pressure is read. To possess it is to save ten times its cost every year at least.

The buyer of a car with low-pressure tyres should make sure that his jack will lift the car the extra two inches or so when the tyre is flat. If it will not he should throw it away and buy the *Dunlop* "Double-Lift" jack, which besides being extremely well made is only 6 in. high when closed. The central pillar consists of a threaded bar within a tube threaded inside and out, which gives a quicker lift than the simple type. The gearing is completely enclosed and the top swivels; the base is broad enough to stand firmly on any surface.

It will save the doctor a great deal of valuable time to make sure he has a good pump. Most men hate the strenuous work of inflating tyres with the ordinary push-and-pull type, and there are several extremely good foot-operated pumps in the show. The two best, which are of similar design, are made one by Dunlops and the other by William Turner and Bro., Ltd., of Sheffield. The latter is called the *Kismet-Duplex* (Fig. 6), and costs 58*s.* 6*d.* in its box. There is a smaller model at 40*s.* A high-pressure cylinder works inside a low-pressure one; air is passing into the tyre all the time, and the work, besides being easy, is cut extremely short, since the pressure is increased about 1½ lb. by each stroke. The valve connexion is of a "universal" push-on type (which, by the way, should be on all pumps. Many designs are marketed by different firms, and cost 2*s.* or 3*s.*).

FIG. 7.



The Smith saloon spotlight.

Shock Absorbers.

The great elasticity of balloon tyres causes an uncomfortable bounce unless the recoil of the spring is damped by some form of shock absorber. There are many good makes, but of these the most generally used are the *Gabriel Snubber* representing the counter-spring principle, and the *Hartford* representing the friction principle. The Gabriel, shown by *Brown Bros.*, consists of a coiled spring in a box on the frame, attached to the axle by a strip of stout webbing. It is extremely efficient, and is fitted to all Morris and Buick cars.

The Hartford, of *T. B. Andre and Co., Ltd.*, London, is so widely known that it hardly needs description. It is shaped like the hind leg of a grasshopper; one arm is bolted to the frame and the other to the axle. Double models are made for racing cars, of which hardly one exists without them. The damping effect is finely adjustable. This fitting makes all the difference to the comfort of a touring car, and adds at least 20 miles per hour to the maximum speed of a racer. For smaller cars it costs between 12 and 15 guineas to fit.

In these days of spare wheels and cord tyres a driver does not often need to mend a tube on the road, but it may easily happen to a country practitioner that he has left a wheel at a garage to be mended and then punctures or bursts one of the others. The only alternative to abandoning the car is to carry a box of *Patchquicks*, which are stout patches that are applied with a special solution called " Fix," like patches on a bicycle tyre. The presence on the car of a box of these patches may save the loss of a half-day's work or more. Always carry valve spares on the car.

Tyre Insurance.

The Lancashire and General Assurance Co., Ltd., 8, Bucklersbury, London, E.C., have a scheme of tyre insurance that will be welcome to many motorists. They insure against bursts at a rate of 6*d.* per £ value. Coupons are sent on application. The scheme applies only to British-made tyres, which must not have run more than a week.

The *Parson's Non-Skid Co.*, in addition to their unique chains which are the only counter to thick mud or snow, showed a neat " Twinbar " bumper at £3 5*s.*, for front or back.

The Industrial Rubber Products make neat india-rubber grips for the steering-wheel at 6*s.* 6*d.*, and *Moseley* a pneumatic driving-cushion, the " Float-on-Air," in all sizes, from 47*s.* 6*d.*

Lights.

C. A. V., *Lucas*, *Rotax*, and all the well-known makers were well represented.

The *Marvulc Accessories Co.* showed a very useful dimmer switch called the " Courtesy," which has the following advantages. It is indestructible and will not burn out, can be used on any system, will give any degree of dimming or switch off entirely, and can be fitted in any position on the car. It costs 15*s.* 6*d.*, and is most convenient on a spoke of the steering-wheel.

S. Smith and Sons, of Great Portland-street, showed among their great range of accessories two very useful lighting devices. The *Saloon Spotlight* (Fig. 7) fits through the wind-screen pillar and is directed without lowering the window by turning a milled knob that projects inside the car and revolves a small friction disc one side of which makes contact with the body of the lamp.

The *Smith Safety Signal Mirror* has a transparent two-ended arrow in the glass. By moving a switch on the dashboard either end will glow red, according to the direction in which the driver intends to turn. Pressure on the foot-brake signals " stop " or " slow " by lighting both heads of the arrow.

Horns.

Alfred Graham and Co., who have fitted our warships for years with loud-speaking telephones, have marketed a new electric horn called the " Sparton S.O.S." The note, although not offensive, is high-pitched and arresting, and extremely loud—the kind of horn that wants a dimming-switch for town.

Klaxon, Ltd., in addition to their large and well-known range of alarm devices, sell a model with two notes, for use either in town or country.

A fitting that should be on every steering-wheel is the *Eural* horn ring. It happens continually that a driver wishes to sound the horn, steer, and pull his brake on at the same time, and no simple switch will allow him to do all three. The Eural ring is attached to the spokes of the wheel, and pressure on any part of it sounds the horn; there is no position of the steering hand that puts it out of reach. It is made in five different diameters, and costs from 21*s.* to 35*s.*

Petrol and Oil.

All the leading makers occupied stands gaily decorated with illuminated petrol-supply pumps and coloured cans, and exhibited samples of their fuel and lubricants. There is hardly any bad petrol to be had, but car-owners should be careful to buy only oil with a thoroughly reputable name, such as Castrol (Wakefield's), Shell, Price's, &c. The British Petroleum Co. are the only purely British suppliers of motor fuel. They are the selling end of the Anglo-Persian Oil Company, which has vast wells in Persia and Iraq.

Ignition.

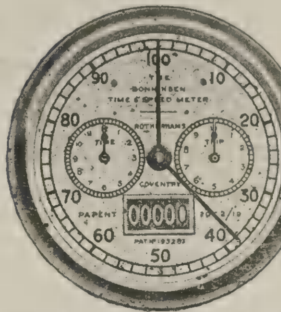
Lodge have a very complete range of plugs, and Smith and Son handle the well-known *K.L.G.*, which was designed originally by the famous racing driver, Kenelm Lee Guinness, and has proved its worth in many races. Both makes are thoroughly reliable.

Simms Motor Units showed several magnetos in action, particularly a slow-speed model which gives an especially hot spark for starting.

Speedometers.

Now that every car is sold with a speed indicator thrown in, owners are probably less interested than they were in descriptions of individual types. There is one so outstandingly good, however, that it would be worth anybody's while to demand it and pay the difference. It is the new Bonniksen Time-Speedmeter (Fig. 8), at £8, from Rotherhams', of Coventry. The Bonniksen speedometer has been known for many years, of course, but the new model is considerably improved. In addition to the two " walking hands," one of which is always steady at the speed to be indicated, there are two small dials, one identical with a clock face and the other like it, but divided into 10 " hours " instead of 12. The first tells the time of actual running and is set by the watch at starting, the second the distance covered in miles. The driver can therefore calculate his exact average speed and know how long he lost in stops. To the careful business-like driver it will appeal irresistibly.

FIG. 8.



Bonniksen time and speed meter.

Miscellaneous.

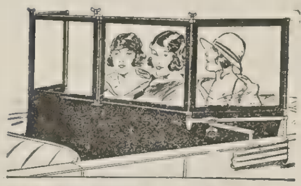
Ferodo, Ltd., are well known for their clutch and brake linings, and the driver who is determined to make his car as comfortable as he can will be interested in the application of their fabric to the leaves of springs. Besides prolonging the life of the springs it damps out the rebound without spoiling the resiliency. It is known as " Ferodo Spring Interleaving."

Among the various devices for preventing thieves from driving a car off are the *Connaught* petrol tap, which can only be turned on by a special key (*Jenks*, 54, Ebury-street, S.W.), and an ingenious electrical lock called the *Owl*, by *E. T. Riches and Co., Ltd.*, 19, Store-street, W.C. It replaces the ignition switch, and is a small round dial, fitted with a revolving ring on which is an inside pointer. The dial itself is marked like the face of a clock, and the mechanism is set at a particular " starting-time " known only to the driver. The engine can only be started if the pointer indicates this time, and any illicit attempt turns on the electric horn. The makers are so confident of its infallibility that they include a free insurance of £25 against theft, and suggest that its mere presence would deter the would-be thief. The American device of a large scarlet wedge, to lock on to the tyre, seems not to have penetrated Olympia yet.

The *Boyce* radiator thermometer, among other reliable makes, is indispensable to a sympathetic driver. In winter engines are driven too cold as often as too hot, and in conjunction with a radiator-jacket by any good accessory maker this fitting will enable him to maintain the best running temperature. It is also extremely ornamental, as a glance at any Morris-Cowley or Buick will show. The temperature of the water is shown by the height of a red column in a circular glass dial with a nickel frame, like a watch. Similar in appearance is the " Telegauge " petrol indicator, by Picard's, which is designed for tanks filled from the scuttle, and shows the contents in gallons.

The "Easting" rear wind-screen (Fig. 9) maintains its popularity. These cleverly designed screens make all the difference to the comfort of passengers in the back of a touring car, and many makers fit them as standard. The type illustrated is a four-panel screen with four-point suspension. The panels are of highly polished transparent celluloid on tubular steel frames covered with leatherette, and beneath them are large waterproof aprons that completely protect the passengers. The two centre panels hinge back as doors on the outside ones, and the screen can be locked rigid in any desired position. It completely fulfils the cardinal requirements of protection, convenience of entrance and exit, and clearness of vision.

FIG. 9.



The Easting rear wind-screen.

The thought suggested most forcibly by this year's Olympia is that the vast car-less public is going to be substantially reduced between now and next midsummer. What the roads will be like does not bear thinking, but it is much more important that a few more thousand Englishmen will have their lives enriched by the adventure of owning and learning to manage a car of their own, and will enter into the possession of our English roads and the country they open up, than which there are few more valuable possessions.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 3RD, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 28; scarlet fever, 2217; diphtheria, 1002; enteric fever, 61; pneumonia, 738; puerperal fever, 59; cerebro-spinal fever, 4; acute poliomyelitis, 15; acute polio-encephalitis, 1; encephalitis lethargica, 43; dysentery, 9; ophthalmia neonatorum, 101. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 23 from measles, 12 from scarlet fever, 28 from whooping-cough, 51 from influenza, and 23 from diphtheria. There were 126 deaths of children under 2 years from diarrhœa and enteritis, as compared with 173, 220, 219, and 230 in the preceding weeks. In London itself the deaths from diarrhœa and enteritis in children under 2 years numbered 34, as compared with 46, 55, 43, and 38 in the preceding weeks; there were 7 deaths from diphtheria, 3 from whooping-cough, and 9 from influenza.

MEDICAL GOLFING SOCIETY.—The annual autumn meeting of this society was held on Oct. 10th and 11th at Deal by permission of the Royal Cinque Ports Club. The course was in excellent condition. The results of the competitions were: Singles *v.* Bogey: L. W. Bathurst, 3 up; 2nd prize, W. H. Lamplough, after a tie with L. Barrington-Ward. Foursomes *v.* Bogey: G. Norman and H. Wolseley-Lewis, 2 down. Canny Ryall Challenge Cup: H. Apperly after a tie with A. H. Vassie at 75; 2nd prize, Mather Thomson, 76; 3rd prize, N. Fleming and H. Gardiner-Hill, 77.

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY, LIMITED.—The annual meeting of this society was held at the offices of the Company, 300, High Holborn, London, W.C., on Oct. 12th. The Chairman, Dr. F. J. Allan, in his annual address, congratulated the members on the satisfactory report on the work of the society during the past year. He called attention to the fact that, though there was a steady increase in the business, the ratio of expenses had fallen by nearly 2 per cent. as compared with the previous year. Dr. Allan gave a brief history of the society since its foundation in 1883, and in referring to the various policies issued, said that the society was converted into a limited company on a mutual basis in 1920, as hitherto it had suffered from the restriction under the Friendly Societies Act, which limited the amount for life insurance to £300. Since the alteration over £500,000 of new business had been transacted in that branch. Dr. F. C. Martley and Sir William Willcox were re-elected to the board of directors, and Messrs. Harber, Sturges, and Fraser were re-elected auditors.

Correspondence.

"Audi alteram partem."

THE UNIVERSITY OF LEEDS: THE MEDICAL FACULTY.

To the Editor of THE LANCET.

SIR,—The old Leeds Medical School is approaching its century of existence in which a steady progress of development has been marked from time to time by substantial additions to its accommodation. Since 1893, the date of completion of the present buildings, there have been no structural alterations commensurate with the progress of physiology and pathology, the closer coöperation of laboratory and clinical departments, and the increase of the general and special hospitals and the public health organisations, which all add to the obligations and opportunities of service of the Medical School.

The support given by the medical profession to the school in times past was both generous and important. The example of former days is our justification, at this critical time of need for expansion, for making a special appeal on behalf of the school.

The University is fully aware of the value of the Leeds Medical School, and desires very earnestly to promote the usefulness of this faculty with no less care and energy than it devotes to the development of the faculties of arts, science, and technology. For this reason the urgent needs of the Faculty of Medicine have been acknowledged by the University; and in making its general appeal to Yorkshire it feels that the greatest assistance may be derived from the spirit of the profession which by its own endeavours raised a medical school from casual meetings in the back room of the old dispensary to a position of respect and eminence in the medical world.

At the present time there is neither accommodation nor equipment to permit the University to set men on to meet the demands for investigation and service required by the community. Even the present staff, honorary and otherwise, are prevented from giving their energies and enthusiasm to current problems by this lack of facilities. It is earnestly hoped that the members of the profession will give all the assistance in their power towards the object of the University which is to make its medical departments capable of acting as a fruitful and useful centre of research and information and equal to their obligations to our large industrial population.

We are, Sir, yours faithfully,

DEVONSHIRE,
Chancellor.

J. KAY JAMIESON,
Dean of the Faculty of Medicine.

The University, Leeds,
October, 1925.

OCCUPATIONAL THERAPY.

To the Editor of THE LANCET.

SIR,—A movement is now actively on foot for the promotion and coördination of all forms of curative handwork in this country. In July last Mr. Thomas Kidner, President of the American Therapy Association, was entertained at the Lyceum Club by men and women in the medical and educational world, when he gave an account of the growth and results of the work of that Association during the six years of its existence. The hope was expressed that an association on somewhat similar lines might be started in this country. Mr. Kidner's report was followed by comments from Sir Robert Jones, Dr. E. Mapother, Dr. Porter Phillips, and Dr. Crichton Miller, which made it clear that while much was being done in this country for tuberculous cases, the psychical side of the work was as yet sadly undeveloped, owing rather to lack of funds and trained workers than to any failure to realise the value of handwork as a means of cure.

As a direct outcome of this meeting, representatives of interested bodies met at 122, Harley-street, London, in September, when Dr. Jane Walker explained the object of the meeting as an effort to ascertain the possibility of forming an association to stimulate and advance the work in this country, by promoting coöperation in already existing work, gathering suggestions and ideas from all sources and disseminating them for the common good, and by aiding in the training and supply of suitable workers. It should be borne in mind, said Dr. Walker, that occupational therapy was of three kinds: *Diversional* therapy, when the patient was not fit for more than simple games or amusements to divert the mind. Or, if further on the road to recovery, the *occupational* type of work could consist in making useful and artistic things, not only for the purpose of occupying the mind, but for the restoration of impaired or weakened function. Thirdly, and this would refer primarily to non-mental cases, the work could be *vocational*, in the attempt to place the patient in a better position to earn his living when restored to health. From the ensuing discussion it became clear that the position in regard to mental patients was held to be quite different from that of the tuberculous. In regard to orthopædic work, Mr. R. C. Elmslie regarded it as impossible to separate the occupational from the vocational. Dr. J. E. Chapman emphasised the distinction between the two. Lieut.-Colonel J. R. Lord's experience of mental cases showed the work had to be undertaken from an entirely curative and non-vocational point of view. Others who contributed to the discussion were Dr. N. D. Bardswell, Mrs. Kimmins (Heritage Craft Schools), Miss L. Nevile (Essex County Association), Miss Evelyn Fox (Central Association for Mental Welfare), and, on the subject of the training of workers, Mrs. Francis Lewis and Miss Munckton.

Three points emerged from this discussion: (1) No doubt exists as to the value, and, indeed, necessity, of handwork as a means of physical and mental cure in cases where recovery is slow and tedious. (2) Both in practice and result, occupational therapy differs widely in the two forms of illness, mental and physical. (3) The need for trained workers is urgent.

Finally, it was proposed by Dr. W. A. Brend (Ministry of Pensions) and carried unanimously that an association be formed, and a provisional committee to consider finance and organisation was appointed as follows: Dr. Jane Walker, Dr. Brend, Mr. William Wilson, D.Sc. (Inspector of Workshops, Ministry of Pensions), Mrs. Townsend (Cripples' Care Committee), Miss Nevile, Miss Fox, with Miss M. Gribble as acting secretary.

As one of the chief aims of this newly-formed Association will be to promote coöperation in existing work and to further new enterprise, it will be of the greatest assistance to the executive committee if heads of institutions or other interested workers would offer suggestions as to the way in which such an association would serve them best in their particular branch of work, and would furnish further details as to what they have been able to accomplish already.

I am, Sir, yours faithfully,

M. GRIBBLE,

Secretary, "Occupational Therapy,"
122, Harley-street, W. 1.

Oct. 7th, 1925.

WHAT CONSTITUTES A CURE IN PSYCHOTHERAPY?

To the Editor of THE LANCET.

SIR,—I read with interest the annotation on this subject in your issue of Oct. 3rd. Personal and subjective factors are of more account in the psychoneuroses and in functional disorders generally than in any other department of medicine. Classification, diagnosis, treatment, and standard of cure are therefore inevitably less cut-and-dried, and statistics are apt to be varied and unreliable. We remove a tumour, and set it up in a bottle of spirit for all the world to see; we remove an obsessive fear which its owner has hidden from all the world but ourselves—and where can we preserve it as evidence? The faulty adaptation to life which is the essence of a psychoneurotic state may be wholly internal, hence the unsupported statement of such a patient as to his illness, improvement, or cure, while not the final word on the matter must be given much more weight than in the case of a sufferer from gross organic disease. A cure can only consist in the patient being enabled to reach a stable adjustment to life, and can only be proved by the harmony and efficiency of his reactions to it and by his freedom from his former mental or physical symptoms.

It must also be remembered that certain persons, capable of leading highly useful and successful lives, suffer from what we can at present only call a constitutional nervous instability, which, from the practical point of view, is in many cases incapable of being influenced by psychotherapy or any other treatment. But just as we may "cure" a case of bronchitis without altering an underlying emphysema, or may, for an indefinite period, relieve dyspnœa and palpitation without affecting a damaged cardiac valve, so we may—and should—do much by psychotherapy to relieve neurotic symptoms even in cases where we may be unable to touch the basic causal factors. In other words, the existence of "chronics" is just as inevitable in psychological work as in ordinary medicine, their frequency no greater, their "cure" just as impossible, and their need for help just as urgent.

It is thus pertinent to ask, What constitutes a *failure* in psychotherapy, for it is certain that much scepticism and distrust are due to the fact that psychotherapy is asked for, and too often attempted, in cases where a total or partial "failure" is a foregone conclusion owing to the nature of the case or its attendant circumstances.

I have not happened to notice any published statistics of individual psychotherapeutic work, so, for what they are worth, I have investigated my own records. I am not in a position to say whether my results are good, bad, or merely absurd. I have taken 100 consecutive cases which have been referred to me for psychotherapeutic treatment, or at least for an opinion as to its advisability, omitting only those which are still under treatment, and a few obviously unsuitable cases, usually of manifest insanity, which have been brought to me without, or against, the advice of their physician. They cover a wide field, from enuresis and simple insomnia to complicated obsessional and anxiety states. I try to believe that I adapt my methods to individual cases. Some have worked out on typical Freudian lines, with others a more constructive kind of mental analysis has proved useful, some have been treated by explanation and discussion, one or two by hypnotic suggestion, due regard being had to the presence in any case of toxic or endocrine factors.

Of the 100 cases under review 16 were more or less promptly declined as unsuitable, without any attempt to institute treatment. The majority were cases of early melancholia or dementia præcox, three showed the mental sequelæ of lethargic encephalitis, two suffered from organic nervous disease. In this branch of medicine, above all others, rapid diagnosis is dangerous and often impossible, and in nine cases I began treatment in a more or less tentative way, but after a period varying from one to six weeks I decided, usually in spite of the patient's wish, to give it up, as it had become apparent that such treatment as I could give would do no real good. Some of these proved to be definitely psychotic, in some of them physical treatment appeared to be the first requirement, in others difficulties connected with their employment, or their domestic relationships were insuperable. It should be said that some at least of these 25 rejected cases could probably have been dealt with successfully in a suitable institution or nursing home had circumstances permitted. I have not included in this series some which I myself sent to such places.

Eight patients whom I would have continued to treat stopped attending, either owing to family opposition or because the demands which treatment made upon their time, pride, courage, honesty, or purse were more than they were prepared to face.

Of the remaining 67 cases treated to a conclusion, I classify 22 as "cured." By that I mean that all symptoms have disappeared, the patients are efficient and happy in their ordinary activities, and, if life treats them with reasonable kindness, I see no grounds for anticipating any relapse.

Twenty I describe as "much improved." (Ten of these state that they are perfectly well, but while encouraging them in that belief, I am not yet myself sufficiently confident as to their stability to include them in the "cured" class.) They have lost most, if not all, of their symptoms, and are getting on with their daily work very comfortably, able to deal fairly adequately with any difficulties which arise.

Seventeen are "improved." They are relieved of their more urgent symptoms, and are carrying on, though not without some difficulty at times. Psychological readjustment is apt to be a slowly progressive matter, and some of them will, I expect achieve it more fully by degrees. Others will probably require further assistance sooner or later.

The remaining eight are complete failures. That is to say, they are cases which, in my opinion, psychotherapy ought to have been able to help more or less, but which have shown no improvement. Apart from lack of skill on my part, the chief reasons for failure appear to be unusual depth and complexity in the psychological maladjustment, and the presence of persistently unfavourable external circumstances.

The obvious criticism of these figures from the statistical point of view is that each case is classified in an arbitrary manner, and largely on subjective grounds, by the unconfirmed testimony of two biased parties, the patient and myself. I grant this unfortunate and unavoidable fact at once, but until the emotional vagaries of the hysteric and the compulsions of the obsessionist can be made as definite and objective as microscopic specimens and death certificates, I do not see how statisticians can ever be given the precise and clean-cut figures and percentages regarding the results of psychotherapeutic work which they quite rightly demand in other departments.

I am, Sir, yours faithfully,

Glasgow, Oct. 12th, 1925. D. Yellowlees.

LUMINAL OR BORAX IN EPILEPSY.

To the Editor of The Lancet.

Sir,—Those who deal with a large number of cases of epilepsy of all the described types, from minor epilepsy and pyknolepsy to affect epilepsy, know that it is not uncommon in adults to find remission from attacks for a few months with almost any of the advised remedies. My chief objections to luminal are: 1. It easily tends to become toxic, of which the symptoms are drowsiness, vertigo, disturbances of coördination and speech, rashes and œdema, and, occasionally, restlessness and excitability. 2. While in most cases which have never previously been given it, attacks are lessened and sometimes cease for a few months, in the vast majority of these cases it rapidly loses its effect and after a few months becomes ineffective.

In my own experience, sodium biborate (borax) is the most valuable therapeutic agent we have for epilepsy if it is properly applied. Since 1920 I have been using it as a routine treatment in every variety of epilepsy, in nearly 100 cases, and even where it does not absolutely cure it greatly reduces the number of attacks. The great objection is that children do not as a rule respond so well as adults. Its whole value lies in the method in which it is given. I start the patient (if an adult) on sodium biborate, gr. 10, thrice daily, with 10 or 15 gr. of sodium bromide. Sometimes I add 2 or 3 minims of liquor arsenicalis, but I am doubtful of the necessity of arsenic. The main combination is bromide and biborate. If the patient does well on this, I leave it. If the fits do not cease in a fortnight (the standard I adopt during treatment is total cessation of fits, not mere diminution in number, except in pyknolepsy), I first of all increase the sodium biborate to 15 gr. thrice daily. If the fits do not cease totally in another fortnight with this I next increase the bromide to 15 gr.—i.e., 15 gr. each of sodium biborate and sodium bromide. I leave it at that for a month or six weeks, and if there are still fits I give them 15 minims of belladonna once daily, either morning or evening, depending on whether the fits are diurnal or nocturnal, in addition to the 15 gr. each of bromide and biborate three times a day.

This combination almost invariably, in my experience, achieves a cessation of fits in adults. Once I get to the optimum drug combination I leave the patient on that for about two months if belladonna has been used, then I diminish the belladonna first, so that after a further month the patient is not taking belladonna. The biborate and bromide I leave undisturbed for at least a year, then if there are still no fits I gradually diminish the bromide, taking some months till the bromide has disappeared altogether. The patient then remains on what is his optimum dose of biborate (10 or 15 gr.), and is kept for another year, even without fits, on sodium biborate and water.

The following cases shown at a recent clinical lecture will serve as illustration.

Mrs. A. B., aged 45. I first saw her on Nov. 10th, 1921. She had had her first fit three years before that and had been under continuous medical treatment. Her fits were now getting more frequent and when first seen she was getting two to three every week. She had no aura. She had incontinence of urine sometimes, bit her tongue, injured herself sometimes, and was always mentally confused afterwards. She was put on sodium biborate gr. 10, ammonium bromide gr. 15, liquor arsenici hydrochlorici minims 3. In the course of the first 12 months under treatment she had only three slight attacks, and her last fit (a mild one) was on Dec. 8th, 1922. The bromide was finally taken out of her mixture on March 1st, 1923, when she was put on a mixture of sodium biborate, gr. 10 and water, three times a day. This was continued till April, 1924, when all medicine was stopped. Since then she has had an attack of pleurisy and one of influenza, but she has had no more fits.

Miss C. D., aged 27, "dull mentally" since birth, and can neither read nor write. She had fits of major epilepsy for several years before coming under my care in January, 1922. They were increasing and she was then having sometimes three in a week. She was put on 10 gr. each of sodium biborate and ammonium bromide thrice daily. Her last attack of major epilepsy was in April, 1922, but she has had what her mother calls "spasms," probably myoclonus epilepsy. She had one of these "spasms" on an average of one every two months, but has not had even a "spasm" since September, 1924. She is still on 10 gr. each of bromide and biborate.

Mr. E. F., aged 26. He has had fits since the age of 11. He has no aura; incontinence of urine sometimes; bites his tongue, injures himself, and is "stupid" for about ten minutes afterwards. His fits averaged one a month, and he had been under treatment at various hospitals for many years. His last fit was on April 7th, 1924. He came under my notice on April 16th, 1924, and I put him on sodium biborate gr. 10, sodium bromide gr. 15, thrice daily. He has not had a fit since he has been under treatment. He is now on 10 gr. of biborate and 5 gr. of bromide. In another month he will be on biborate alone. His general health has improved and he feels well. His heart exhibits premature contractions at irregular intervals, 1 in 4 or 5, to 1 in about 50 beats, but he has no dyspnœa or palpitation.

On the whole I find that patients bear sodium biborate well, and I have yet to find one suffering to any extent from indigestion due to it. The only toxic effect I have noted is that the heart frequently exhibits premature contractions, which can be ignored, as the patients do not suffer either from dyspnœa or palpitation.

I am, Sir, yours faithfully,

Philip Figdor, M.B.,
Assistant Physician, London Temperance Hospital, &c.

Oct. 7th, 1925.

LUMINAL IN EPILEPSY.

To the Editor of The Lancet.

Sir,—I have before me the case-records of 89 epileptics treated during the last two and a half years at the Birmingham and Midland Hospital for Nervous Diseases. Careful records of progress and treatment are kept in all cases of epilepsy at this hospital, so that the case-sheets constitute a valuable guide to the merits of different forms of treatment. Of the 89 cases, 40 per cent. attended at fortnightly intervals for over 12 months, another 45 per cent. for over six months, and the rest for short periods only.

From a study of these cases four facts seem to emerge: (1) That luminal is more effective than bromide in controlling the seizures in idiopathic epilepsy; (2) that the effect of luminal is considerably enhanced by the addition of a small dose of bromide; (3) that the mentality of the patient improves under luminal, as compared with bromide; and (4) that although the period of improvement under luminal is longer than under bromide, tolerance seems eventually to be established and fits recur.

As to dosage, I do not believe that more than 3 gr. of luminal daily should be given in epilepsy. In only five cases of this series was this dose exceeded, 1½ gr. having been given three times a day, and in every case signs of intoxication appeared—that is, thick speech, ataxia, hilarity, and a subjective sensation of "silly-headedness." In no case were skin rashes noted. I do not believe that luminal can ever replace bromide entirely, but I think its great utility is to enable us to so reduce the dose of bromide that the characteristic bromide depression does not occur. Also, since it is given in tabloid form it is so much more convenient to take. I have omitted special features, such as family history, the presence of disease in other systems, reflex sources of irritation, and, what is still more important, the time which has elapsed between the onset of fits and the institution of treatment, but all these have been taken into account in deciding the merit of luminal as compared with bromide.

Dr. O. G. Misquith quotes two cases from his practice in which luminal completely checked the fits and restored the patients to a "normal existence." I, too, have had such cases, in which it appeared to act like magic, cases in which bromides had seemed actually to aggravate the trouble. I remember one such case in a tram conductor, who had lost his employment on account of fits, and who, when he consulted me, was having 5 to 10 seizures a week. Luminal in his case completely checked the fits, and for months he would bounce into my consulting-room at the hospital, and literally sing his praises from a new-found vitality and joy in life. Alas, this lasted exactly 12 months, and then the fits began to recur, and try as I might by readjustment of dosage, I could not again control him with luminal. I could quote many similar cases.

Cases in which fits begin between the ages of 14 and 20 seem by our statistics to be the easiest to control, and I am a firm believer in bringing all recent cases of epilepsy under a preliminary in-patient observation and treatment before beginning out-patient attendance. Some remarkable facts in this connexion are brought to light by a study of this series of cases.

I am, Sir, yours faithfully,
A. Williams-Walker, M.D., M.R.C.P.,
Physician to Out-patients, Birmingham and Midland Hospital for Nervous Diseases (associated with Queen's Hospital, Birmingham).
Oct. 10th, 1925.

STICKING-PLASTER DERMATITIS.

To the Editor of The Lancet.

Sir,—The annotation on this subject in your issue of Oct. 10th is important. It is to be hoped that Dr. H. W. Siemens has isolated the injurious ingredient. If it can be omitted from the plaster he will have conferred a great boon on countless patients. Recently I was conducting a number of experiments on the skin of my arms and of some colleagues; the ordinary brown hospital plaster was used to retain the applications in position. Invariably, a day or two later, the parts touched by the plaster broke out in discrete follicular pustules. These confused and vitiated any conclusions one might draw from the effects of the materials we were testing. The use of plaster necessarily had to be discontinued.[1] There did not appear to be any sensitising effect from the plaster. All the experimenters seemed equally liable. The eruptions were strictly localised, and the strength and severity of the inflammation produced apparently varied with the length of application.

I am, Sir, yours faithfully,
Wigan, Oct. 12th, 1925. R. Prosser White.

Obituary.

ARTHUR GORDON JENNER, M.R.C.S. Eng., D.P.H. Liverp.

Dr. A. G. Jenner, medical officer of health for the Borough of Stockport, who died on Oct. 5th at the age of 40, studied medicine at the University of Liverpool, qualifying in 1907, and in 1911 he obtained the Liverpool Diploma of Public Health. He held successively the posts of house surgeon and senior house physician at the Royal Southern Hospital, Liverpool, and was then appointed resident medical officer at the West Derby Union Infirmary, Liverpool. For two years he was resident medical officer at the Liverpool Corporation Park Hill Fever Hospital, and in 1912 was appointed assistant medical officer of Burton-on-Trent. Just before the outbreak of the war he went to Stockport as tuberculosis officer, and was appointed deputy medical officer in the early part of 1915. For two years he had charge of the public health in Stockport, and in 1917 joined the Army, where, until 1919, he served with the rank of captain on the administrative staff of the Salonika Army in charge of the 98th and 131st Sanitary Sections. On his return to Stockport he was reappointed deputy M.O.H. in October, 1920. He succeeded the late Dr. H. E. Corbin as medical officer of health for Stockport in 1922. Dr. Jenner was a member of the Board of Directors of the Stockport County Football Club, and was himself an enthusiastic footballer, having been a Rugby player. He was a most efficient and painstaking medical officer, and he was particularly interested in child welfare. A man of pleasing and attractive personality, his early death is deeply regretted by the whole community of Stockport. He leaves a widow and two children.

PERCY ROBERT COOPER, M.D., B.Sc. (Hons.) Lond., F.R.C.S. Eng.

Dr. P. R. Cooper, honorary consulting surgeon to the Altrincham General Hospital, died on Oct. 10th as the result of septic poisoning contracted in the course of his professional duties. He received his medical training at the University of Manchester and at St. Bartholomew's Hospital, London, graduating M.B., Ch.B. Vict. in 1893 and obtaining the M.R.C.S. Eng. and L.R.C.P. Lond. in the same year. In 1890 he gained the B.Sc. of London University with honours, and in 1895 he became a Fellow of the Royal College of Surgeons of England. The following year he obtained the M.B. Lond. with first-class honours, and in 1901 became M.D. Lond. With a strong leaning towards natural history, he was for a time assistant demonstrator in zoology and pathology at Owens College, Manchester, and after some experience as a house surgeon in the Manchester Royal Infirmary he took up practice in Altrincham, where in due course he became one of the best-known and busiest practitioners in North Cheshire. Two years ago he was appointed honorary surgeon to the Altrincham General Hospital. Dr. Cooper was an enthusiastic member of the medical and pathological societies of Manchester, and at one time acted as President of the Manchester Clinical Society. He was a great reader of medical books and occasionally contributed a well-considered note on some clinical problem to a medical journal. The joint library of the Manchester Medical Society and the University Medical School owed much to his interest and coöperation. Altogether he will be much missed.

---

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations held recently the following candidates were successful :—

DIPLOMA IN PUBLIC HEALTH.

Old Regulations : John R. Hayman ; James A. G. Keddie ; William B. Stott, Christ's. *New Regulations :* Andrew N. Fergus ; Mary K. Henegan ; Reginald A. Mansell, Emm. ; Charles F. Pedley, Jesus ; Charles J. Stocker, Trin. (distinguished in Part I.) ; Francis C. Tibbs ; and Man K. Yue, Christ's (distinguished in Part II.).

DIPLOMA IN HYGIENE.

Abdel R. Hassan and Labib Shehata.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The third award of the Streatfeild Research Scholarship has been made by the executive committee of the College to Mr. Norman Leslie Capener, F.R.C.S. This scholarship was founded in 1916 through the generosity of Mrs. Eliza Streatfeild, who gave the sum of £10,000 to the Royal College of Physicians and the Royal College of Surgeons, the income thereof to be expended upon the promotion of research in medicine and surgery. The subject of Mr. Capener's research will be the Comparative Anatomy and Function of the Prostate Gland. The research will be carried out at St. Bartholomew's Hospital and the Zoological Society.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council on Oct. 8th, Sir John Bland-Sutton, President, in the chair, the annual report of the Council to be submitted to the Fellows and Members at the annual meeting on Thursday, Nov. 19th, was submitted, approved, and adopted.—The President reported that a Sir Gilbert Blane Medal had been awarded to the following medical officer of the Royal Navy : Surg. Lieut.-Commdr. Lionel Frederick Strugnell, promotion examination, 1925.—The President also reported that the Bradshaw Lecture on Gastro-jejunostomy would be delivered by Mr. James Sherren on Wednesday, Nov. 11th, at 5 P.M. ; and that the Thomas Vicary lecture on the Mediæval Conception of the Anatomy and Physiology of the Central Nervous System would be delivered by Prof. William Wright on Wednesday, Nov. 18th, at 5 P.M., at the College.—Diplomas of Member were conferred upon the following candidates who have complied with the by-laws of the College :—

K. Bandaly, Cairo and Univ. Coll. ; Leighton M. Clark, King's Coll. Hosp. ; Andrew N. Coomaraswamy, Madras and London Hosp. ; Gerald N. Golden, London Hosp. ; Tom A. Griffiths, Cardiff and Liverpool University ; Allan B. Hewlett, King's Coll. Hosp. ; Thomas Kemp Homer, Birmingham University ; and Elizabeth M. Weideman, St. Mary's Hosp.

VICTORIA UNIVERSITY OF MANCHESTER.—At the examination for the Diploma in Public Health, held recently, the following candidates were successful :—

Part II.—R. B. Boston, P. D. Connolly, E. R. Gilmore, and A. C. Newman.
Part I.—Georgie I. Brodie and Margaret Sproul.

THE Council of the British Empire Cancer Campaign has approved a grant of £1000 a year for six years to Dr. Thomas Lumsden, at the Lister Institute of Preventive Medicine, to enable him to continue the experimental work on cancer antisera reported in THE LANCET of Feb. 21st and Sept. 12th, 1925. Further grants have also been made to Dr. J. C. Mottram, Dr. Louis Cassidy, and Prof. R. T. Leiper.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A lecture on the Diagnosis of Pulmonary Tuberculosis will be delivered by Dr. Marcus Paterson in the Lecture Hall of the Medical Society of London, 11, Chandos-street, on Monday, Oct. 19th, at 5.30 P.M., and all members of the medical profession will be welcome. Several special courses have been arranged for the month of November. The Chelsea Hospital will hold a three weeks' course from Nov. 2nd, consisting of demonstrations, operations, and lectures by members of the staff. Throughout the month the London Lock Hospital has arranged a comprehensive course in venereal diseases. The Royal Waterloo Hospital will give a course in Medicine, Surgery, and Gynæcology from Nov. 23rd to Dec. 12th, embracing the study of diseases of children and women from all aspects. From Nov. 3rd to 28th Dr. Porter Phillips and Dr. Thomas Beaton will give twice weekly lecture-demonstrations on Psychological Medicine. An evening course for general practitioners has been arranged at the London Temperance Hospital from Nov. 1st to 13th. There will be a course in Diseases of the Chest, Heart, and Lungs at the Victoria Park Hospital from Nov. 9th to 21st. Application for copies of each of the syllabus and for the general programme should be made to the Secretary, at 1, Wimpole-street, London, W. 1.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—A meeting of this association will be held at 11, Chandos-street, Cavendish-square, W., on Friday, Nov. 6th, at 4.45 P.M., when Dr. A. I. Simey will read a paper on the Prophylaxis of Common Colds.

A CONFERENCE on Social Insurance in its national and international aspects is to be held under the auspices of the League of Nations Union from Nov. 23rd–26th at the London School of Economics. Sessions of the Conference will deal with the following aspects of the problem : The Government pensions scheme ; the unification of social insurance ; health insurance ; workmen's compensation and accident prevention ; unemployment insurance ; family insurance ; and the international aspects of social insurance. Full particulars of the Conference may be obtained from the Secretary, League of Nations Union, 15, Grosvenor-crescent, S.W. 1.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The report presented at the 101st annual general meeting of the Clerical, Medical, and General Life Assurance Society, held at 15, St. James's-square, London, on Oct. 9th, showed that during the year 1889 new assurances were made for a total sum of £1,616,869, while re-assurances were effected to the extent of £227,500, making the net new life business £1,389,369, as compared with £1,324,691 in the previous year. The total premium income was £672,332, or an increase of £62,840. The claims by death amounted to £352,610, an increase of £3873 over the previous year, which is accounted for by the expansion of the business of the Society. The expenses of management, after allowing for the cost of annuity business, represented £14 7*s.* 5*d.* per cent. of the premium income. As a result of the year's transactions the Life Assurance Fund increased from £7,961,035 to £8,464,681. This growth of £503,646 exceeds that of any previous year.

DENTAL BOARD OF THE UNITED KINGDOM.—A course of four lectures (illustrated by lantern slides) on General Anæsthesia will be delivered during the forthcoming winter season. The series will consist of the following : (1) Respiration in Anæsthesia, and (2) the Absorption and Elimination of Volatile Substances in the Lungs, by Prof. Yandell Henderson, Yale University ; (3) the Circulatory Changes in Anæsthesia, and the Use of Oxygen, by Dr. Leonard Hill ; (4) the Metabolic Changes in Chloroform Poisoning, by Prof. Noel Paton. The lectures will be given in :—London : In the Robert Barnes Hall, the Royal Society of Medicine, 1, Wimpole-street, W., at 8.30 P.M., on Oct. 22nd, 23rd, and 30th, and Jan. 11th. Manchester : In the Medical School, the University Buildings, Oxford-road, at 5.30 P.M. on Oct. 26th and 27th, Nov. 3rd, and Jan. 13th. Edinburgh : In the Surgery Theatre, the University, at 5 P.M., on Oct. 29th and 30th, Nov. 5th, and Jan. 15th. The course is intended primarily for dentists and medical practitioners. Dental students are invited to attend. Tickets of admission are not required.

LIVERPOOL MEDICAL INSTITUTION.—On Thursday, Oct. 8th, the members of this society met to offer their congratulations to no fewer than three of their number on the completion of 50 years' membership. These were Dr. A. Craigmile, of Wallasey ; Dr. A. C. E. Harris, of Birkenhead ; and Mr. F. T. Paul. Allusion was made to the large part played by Dr. Craigmile in the foundation of the Victoria Central Hospital, Wallasey, and to the leading position taken now for many years by Dr. Harris in the profession in Birkenhead. Mr. Rushton Parker and Mr. T. H. Bickerton recalled their experiences of Mr. Paul's earlier days, when he went to Liverpool as resident medical officer and superintendent at the Royal Infirmary, duties now carried out by 11 different individuals. The surgeons of the city had combined to have a number of Paul's " Selected Papers " published as a tribute of their respect and admiration for the man and his work, and at the close of the meeting a formal presentation of this was made.

NEW STOKE-ON-TRENT POOR-LAW HOSPITAL.—The Stoke-on-Trent guardians have approved in principle a scheme for the erection of a new Poor-law hospital which, it is stated, will cost £500,000. The scheme provides for the erection of a hospital at Stoke with 400 beds, capable of expansion to 800, together with all the other adjuncts of a great modern hospital. The decision was arrived at after a favourable report by Dr. F. W. Ellis, chief medical officer of the Birmingham Union, based upon an inspection of the existing institutions at Tunstall and Stoke. Dr. Ellis strongly recommended the centralisation of hospital services for Poor-law purposes by transferring the patients to the Stoke institution and the building of the new hospital there. He suggested that the new hospital should be utilised for the treatment of acute cases, and that the two existing ones should be retained for chronic sick and infirm cases.

THE Wellcome Historical Medical Museum, 54A, Wigmore-street, W., will be closed for cleaning and structural alterations from Oct. 19th until Nov. 30th.

TUBERCULOSIS SOCIETY.—A meeting of this society will be held to-day (Friday) at 8 P.M., at 1, Upper Montague-street, Russell-square, London, W.C., when Dr. F. G. Chandler will read a paper on Pulmonary Tuberculosis in Children.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY. The first meeting of the session will be held on Friday, Oct. 23rd, at the Royal Devon and Exeter Hospital, Exeter, the President, Mr. J. M. Ackland, in the chair. An address will be given by Sir StClair Thomson on the Surgical Anatomy of the Nose and Accessory Sinuses.

THE death has occurred at Hampstead on Oct. 10th of Dr. C. F. Sonntag, Prosector to the Zoological Society and demonstrator in anatomy at University College. Dr. Sonntag was at one time medical officer to the Great Portland-street Red Cross Clinic for Disabled Officers, and recently published a standard work on the Morphology and Evolution of the Apes and Man.

UNIVERSITY OF EDINBURGH: CAMERON PRIZE LECTURES.—Prof. Harvey Cushing, who was awarded the Cameron Prize of 1924, will deliver three lectures in the Anatomy Class-room, University New Buildings, on the undermentioned dates at 4 P.M.:—Monday, Oct. 19th: The Circulation of the Cerebro-spinal Fluid; chairman, Sir E. Sharpey Schafer. Tuesday, Oct. 20th: The Pituitary Gland; chairman, Sir J. Alfred Ewing. Thursday, Oct. 22nd: Brain Tumours; chairman, Sir Harold J. Stiles. Students and graduates in medicine are invited to attend.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.—Following the opening lecture of the winter session by Dr. William Hill on Oct. 6th, the annual dinner of the medical staff was held at the Trocadero Restaurant the next evening, Mr. Harold Kisch in the chair. A total of 52 were present, and amongst the guests were: The lecturer, Dr. W. Hill; the President of the Royal Society of Medicine, Sir StClair Thomson; the President of the Fellowship of Medicine, Sir William Arbuthnot Lane; Sir Thomas Horder; the President of the Laryngological Section, Royal Society of Medicine, Dr. W. H. Kelson; the Honorary Secretary of the Fellowship of Medicine, Mr. Herbert Paterson; Mr. Herbert Tilley; Mr. G. J. Badgerow; Mr. T. B. Layton; Dr. Watson-Williams; Dr. J. H. Chaldecott; and the Chairman of the Committee of Management of the Hospital, Mr. Carmichael Thomas, with his colleagues, Mr. Mackillop Brown and Mr. Glenton Lewis.

LIVERPOOL: VISIT OF THE MINISTER OF HEALTH.—During a two days' visit to this city Mr. Neville Chamberlain busied himself chiefly with the inspection of the new housing and re-housing problems of Liverpool. The site for the proposed ten-story tenement was visited, and at the dinner in the town hall on Oct. 8th he expressed himself as profoundly impressed with the boldness and courage with which the subject had been faced, and more particularly for the imagination shown in planning communications between the newer areas and the centre of the town. He also advanced the consideration as to whether the time had not come when great communities should consider a change of ownership of slum property, substituting for a landlord, unwilling or unable to fulfil his responsibility, one which has ample resources and a sense of public duty. On the second day Mr. Chamberlain visited the various institutions under the guardians and also the municipal hospital at Fazakerley for infectious diseases, including phthisis and surgical tuberculosis. At the latter institution he spoke of his sympathy with the campaign for a plentiful, clean, tubercle-free milk-supply, and also promised to see that, so far as the financial condition of the country would allow, a due proportion of the Government's resources was secured for the extension of the campaign against tuberculosis, above all for the treatment of the disease in childhood.

Hospitals Contributory Scheme.—At a recent meeting of the Liverpool Hospital Staffs' Association the opportunity was taken of drafting certain resolutions bearing upon the proposed Lord Mayor's contributory scheme for the support of the voluntary hospitals, which is modelled largely upon the Sheffield "penny-in-the-pound" idea. The following points were emphasised: (1) That there should be no differentiation in treatment between contributors and non-contributors; (2) that it should be recognised that contributors should attend the hospitals only with the knowledge of their private medical attendant, except in cases of urgency; (3) that in any contract entered into by hospital authorities for the provision of medical services provision should be made for the payment of a certain proportion into a medical staff fund. It was noteworthy that these points, after full discussion, were agreed to unanimously by the meeting, at which all the hospitals were fully represented.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Oct. 20th.

GENERAL MEETING OF FELLOWS: at 5.30 P.M.
Ballot for election to the Fellowship.

PATHOLOGY: at 8.30 P.M.
Papers:
W. Cramer: Systemic Factors in Carcinogenesis.
C. C. Okell and H. J. Parish: Virulence Testing of the Diphtheria Bacillus.

Wednesday, Oct. 21st.

HISTORY OF MEDICINE: at 5 P.M.
Paper:
Dr. J. D. Rolleston (President): Voltaire and Medicine. Part I.

SURGERY: at 8.30 P.M.
Presidential Address:
Sir Lenthal Cheatle: The Present State of the Teaching and Practice of Surgery.

Friday, Oct. 23rd.

STUDY OF DISEASE IN CHILDREN: at 5 P.M. (Cases at 4.30 P.M.)
Cases:
Dr. C. Worster-Drought: Case of Hirschsprung's Disease with Double Optic Atrophy.
Dr. C. Worster-Drought (shown by Dr. E. W. Fulton): Case of Incoördination, for Diagnosis.
Mr. W. E. Tanner: Congenital Malformation of Tongue and Pharynx.
Dr. D. Paterson: Old Case of Cœliac Disease.
Dr. N. Hobhouse: Lesion of Mid-Brain and Pons.

EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.
Paper:
Dr. T. Stacey Wilson: On the Management of Scarlatinal Epidemics in Boarding Schools (illustrated by photographs of Desquamation, Scarlatinal and otherwise).

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.
WEDNESDAY, Oct. 21st.—4.30 P.M. (at St. John's Hospital, Leicester-square), Pathological Specimens and Clinical Cases. 5 P.M., Dr. Knowsley Sibley: Treatment of Diseases of the Skin by Ultra-violet Rays.
The Monthly Dinner will be held at the Cavour Restaurant, Leicester-square, at 6.30 P.M. Price 7*s.* 6*d.* per head.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 19th, to SATURDAY, Oct. 24th.—Fellowship of Medicine Lecture, Medical Society, 11, Chandos-street, Mon., 5.30, Dr. Marcus Paterson: The Diagnosis of Pulmonary Tuberculosis. — COMBINED CHILDREN'S COURSE, Paddington Green Children's Hospital, Victoria Hospital, and Children's Clinic. Morning and afternoon sessions.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road. Special Course in Laryngology, Rhinology, and Otology. Clinical course and Operative Surgery course, of which one or both may be taken (second week).—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens. Tuesday and Thursday, Clinical demonstration by Dr. G. C. Low and Dr. Manson-Bahr at 2.—ST. PETER'S HOSPITAL, Henrietta-street. Special course in Urology. Clinical work every afternoon and lecture.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
THURSDAY, Oct. 22nd.—3 P.M., Demonstration: The X Ray Examination of Pulmonary Tuberculosis. 4.30 P.M., Lecture: The Treatment of Pulmonary Tuberculosis with Special Reference to Artificial Pneumothorax.
Daily: In-patient and Out-patient Clinics in General and Special Departments, Operations, &c.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Oct. 22nd.—4 P.M., Dr. Frew: Acidosis.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, Oct. 20th.—5 P.M., Dr. H. W. Barber: Bacteriology and Mycology.
THURSDAY.—5 P.M., Dr. J. M. H. MacLeod: Morphology and Histopathology of Elementary Lesions.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 20th.—4.15 P.M., Dr. C. H. Melland: Some Tropical Diseases.
FRIDAY.—4.15 P.M., Prof. W. L. Bragg: X Rays.

ANCOATS HOSPITAL POST-GRADUATE LECTURES.
THURSDAY, Oct. 22nd.—4.15 P.M., Mr. E. E. Hughes: The Significance of Urinary Symptoms.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: October-November, 1925.

Clinical Lectures and Demonstrations.

Monday, Oct. 19th.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., An Introduction to the Study of Aphasia: Dr. Kinnier Wilson.

Tuesday, Oct. 20th.—2 p.m., Out-patient Clinic: Dr. Walshe. 3.30 p.m., Compression Paraplegia from a Surgical Standpoint: Mr. Armour.

Thursday, Oct. 22nd.—2 p.m., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 p.m., Ocular Palsies: Dr. Gordon Holmes.

Friday, Oct. 23rd.—2 p.m., Out-patient Clinic: Dr. Adie. 3.30 p.m., Demonstration of Swedish Remedial Exercises (in Exercise Room): Mr. Elmquist.

The fee for the Course, including Pathology Lectures, is £5 5*s*. For those who hold Perpetual Tickets the fee is £3 3*s*.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Thursday, Oct. 22nd.—12 noon, Ischæmia: Dr. J. G. Greenfield.

Course of Lectures and Demonstrations on the Anatomy and Physiology of the Nervous System.

Monday, Oct. 19th.—12 noon, The Spinal Cord (continued): Dr. J. L. Birley.

Dr. H. J. MacBride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 a.m. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2*s*. (commencing Tuesday, Oct. 20th).

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Oct. 21st.—4 p.m., Dr. M. B. Ray: The Prevention and Arrest of Rheumatic Disease.

PEOPLE'S LEAGUE OF HEALTH, Fyvie Hall, Regent-street Polytechnic.

Friday, Oct. 23rd.—6 p.m., Mr. E. B. Turner: Recreation and Physical Exercise.

Appointments.

Glennie, J. A. R., M.B., C.M. Aberd., has been appointed one of the Medical Referees under the Workmen's Compensation Act for the Districts of the Camelford, Holsworthy, and Launceston County Courts.

MacAdam, W., M.D. Glasg., M.R.C.P. Lond., Honorary Assistant Physician to the Leeds General Infirmary.

Oldham, J. B., M.B., Ch.B. Liverp., F.R.C.S. Eng., Honorary Assistant Surgeon to the David Lewis Northern Hospital, Liverpool.

Toogood, F. S., M.D. Lond., one of the Medical Referees under the Workmen's Compensation Act for the Districts of the Bodmin and Liskeard County Courts.

St. Mary's Hospitals, Manchester: Brentnall, C. P., M.B., Ch.B. Liverp., Honorary Assistant Surgeon; Pope, S., M.B., Ch.B. Manch., and Crowther, J. A., M.B., Ch.B. Manch., House Surgeons at the Whitworth-street West Hospital; Adam, R. S., M.B., Ch.B. Manch., House Surgeon at the High-street Hospital; Craig, Jennie D., M.B., Ch.B., Assistant Medical Officer, Out-patient Department; Knight, Barbara M., M.B., Ch.B., Clinical Assistant.

Certifying Surgeons under the Factory and Workshop Acts: Hoey, J. T. S., M.B., B.Ch. Oxf. (Petersfield); Graham, J. (East Grinstead); Morris-Jones, J. H., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg. (Colwyn Bay); and Webb, H., L.R.C.P. Lond., M.R.C.S. (Bexhill).

Vacancies.

For further information refer to the advertisement columns.

Barry Urban District Council.—H.S. At rate of £200.

Birmingham, Highbury Group of Hospitals.—Jun. Surg. O. £350.

Birmingham, St. Chad's Hospital.—Res. M.O. £100.

Bolton County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Brighton, New Sussex Hospital for Women and Children.—Hon. Asst. Anæst.

Brighton, Royal Sussex County Hospital.—Hon. M.O. for Dis. of Ear, &c.

City of London Hospital for Diseases of the Heart, Victoria Park, E.—H.P. at rate of £100.

Colwyn Bay and Colwyn Urban District Council.—M.O.H., &c. £800.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. At rate of £175.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.P. At rate of £125.

Essex Administrative County.—Asst. Tuberc. O. £600.

Greenwich, Dreadnought Hospital.—S. in charge of Out-patients.

Hospital for Sick Children, Great Ormond-street, W.C.—Med. Reg. and Pathologist. £300.

Hospital for Women, Soho-square, S.W.—Pathologist and Reg. £100.

Liverpool Hospital for Consumption and Diseases of Chest, Mount Pleasant.—Hon. Asst. P.

Metropolitan Hospital, Kingsland-road, E.—Sen. and Jun. H.P. Sen. and Jun. H.S. Also Two Cas. O.'s. Each at rate of £100.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Res. M.O. £200.

Newark Hospital and Dispensary.—Res. H.S.

Poplar Hospital for Accidents, East India Dock-road, E.—Second Res. Surg. O. £175.

Prestwich County Mental Hospital, near Manchester.—Med. Supt. £800.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.

Rochester, St. Bartholomew's Hospital.—Third Res. M.O. At rate of £200.

Royal Chest Hospital, City-road, E.C.—Phys. to Out-patients. £50.

Royal London Ophthalmic Hospital, City-road, E.C.—Sen. H.S. £150.

St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C.—Pathologist. £100.

St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. and Asst. Res. M.O. At rate of £175 and £130 respectively.

Stoke-on-Trent, North Staffs. Royal Infirmary.—H.S. £150. Also H.P. £125.

Seychelles Government.—Asst. M.O. and Res. S. Rs.6500.

Births, Marriages, and Deaths.

BIRTHS.

Heywood-Waddington.—On Oct. 5th, at St. Catherine's-road, Littlehampton, to Dr. and Mrs. Heywood-Waddington—a daughter.

Murphy.—On Oct. 7th, the wife of James Murphy, M.B.E., F.R.C.S.E., Middlewich, of a daughter.

Richardson.—On Oct. 6th, at Edinburgh, the wife of Major D. T. Richardson, R.A.M.C., of a daughter.

Urquhart.—On Oct. 12th, at the Little House, Farnham, Surrey, the wife of J. L. T. Urquhart, L.D.S. R.C.S., of a son.

MARRIAGES.

Chavasse—Jackson.—On Oct. 14th, at St. John's, Putney, Charles Cecil Howard, M.A., B.M. Oxf., son of Mr. and Mrs R. E. Chavasse, of Barnards Green House, Great Malvern, to Mabel, daughter of the late Mr. Jackson and Mrs. Jackson, of 67, Clarendon-road, Putney.

McKendrick—Evans.—On Oct. 7th, at St. Martin-in-the-Fields, William McKendrick, M.B., Ch.B., to Dorothy, third daughter of Howell T. Evans, M.R.C.S., and Mrs. Evans, The Laurels, Blackwood, Mon.

Snodgrass—Owen.—On Oct. 3rd, at St. Saviour's Church, Walton-street, S.W., Captain William McElrea Snodgrass, M.C., R.A.M.C., to Kathleen, elder daughter of A. D. Owen, of Pont-street, S.W.

Walker—Clouston.—On Oct. 6th, at Frodingham Parish Church, Arnold Learoyd Walker, M.A., M.B., B.Ch., to Gwenville, youngest daughter of the late Mr. and Mrs. J. Clouston, of Middlesbrough.

Watson—Lea.—On Sept. 15th, at Christ Church, Mussoorie, Major W. L. Watson, O.B.E., I.M.S., Meerut, to Dorothy Ellen, eldest daughter of Mrs. H. Lea, Burton-on-Trent, and the late Henry Lea.

Wilson—Ellicock.—On Oct. 7th, at Holy Trinity Church, Aldershot, Captain J. A. Lawther Wilson, R.A.M.C., to Gladys Vera, daughter of Captain Ellicock, Aldershot.

DEATHS.

Cooper.—On Oct. 10th, Percy Robert Cooper, M.D., F.R.C.S., of Glenthorne, Bowdon, Cheshire.

Lawrie.—On Oct. 8th, from pneumonia, Alexander Lawrie, M.B., Ch.B., of Hither Green-lane, S.E.

Prest.—At Glenafton, New Cumnock, Ayrshire, on Oct. 8th, Jessie Annie (née Creighton), the loved wife of Edward Ernest Prest, M.D.

Serpell.—On Oct. 11th, at nursing home in Plymouth after operation, Hugh Hamilton Serpell, M.R.C.S., L.R.C.P., late Lieut.-Colonel R.A.M.C., of Polyphant House, Lewannick, Cornwall, aged 48.

Sonntag.—On Oct. 10th, at his residence, Belsize Park-gardens, N.W., Charles Frederick Sonntag, M.D., Ch.B. Edin., Prosector to the Zoological Society of London.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

His Majesty the King's Royal licence and authority has been granted to Dr. Percy Glyn Savours Williams, Principal Medical Officer of Health, Cairo City, to wear the decoration of the Order of Ismail, Insignia of the Third Class, which has been conferred on him by the King of Egypt.

Notes, Comments, and Abstracts.

HOSPITALS, GENERAL AND SPECIAL.*

BY N. BISHOP HARMAN, M.B. CAMB., F.R.C.S. ENG.,
SENIOR OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL, ETC.

The Question at Issue.

THE part that should be played by general and special hospitals in a comprehensive hospital organisation is a matter of growing interest. It is of interest whether the problem be viewed from the national or local standpoint. Hospital organisers must necessarily view the problem as it applies to the area of their work, but these same workers should on occasion take the larger view of national requirements, and envisage the problem as it appears to those whose duty it is to strive to adjust the demands of area and area. Few areas can or do stand alone. Modern facilities for intercommunication have laid flat the boundaries of formerly self-contained areas, so that there can be found but few which can now claim that they are independent of the greater whole. It is well at the outset to define our terms, and to do so in relation to present-day practice. Whatever the connotation of the terms may have been in the past, we now use the words "general" and "special" in a strictly regular manner. We mean by a general hospital one that admits to its services all kinds, or almost all kinds, of disease in any age or sex; and we mean by a special hospital one that restricts its services to one type of disease or one type of patient as defined by age or sex. The question at issue is the relative advantage or disadvantage of such general or special hospitals.

Origin of Hospital Types.

It is of interest to look back upon the origin of these types of hospitals. The earliest hospitals were almost entirely general hospitals. They admitted to their services patients suffering from any kind of disease that needed treatment. Special hospitals are for the most part of modern origin. In the early decades of the nineteenth century, concurrent with the rapid increase of industry in this country and the growth of large urban populations, there was an equally rapid development of medical science. There was an increasing knowledge of and ability to treat general diseases, and also an immense development in the recognition of and skill in the treatment of disease of special regions of the body. The advance was so rapid that large additional clinical facilities were needed. In this country, where the enthusiasm and energy of volunteer works have always blazed the path of progress and brought new fields of work into cultivation, the process of development of hospital service followed what is to us the natural mode. For instance, keen workers in the field of eye diseases started clinics, or dispensaries as most of them were first called, for the treatment of these diseases. One or two doctors in association established in a small way in some convenient house an institution which later has become a recognised eye hospital. This is the story of most of our best known ophthalmic hospitals—e.g., Moorfields in London; the hospitals in Edinburgh, Glasgow, Oxford, and Maidstone, to cite only a few.

It would appear that there was no idea in the minds of these early founders of special hospitals of separation or isolation from or competition with general hospitals. There was a need, so they proceeded to meet it in the simplest way. To expand an existing institution was or might be difficult. To set up something new was easy, and the new made a ready appeal to philanthropists. This method of working accounts for conditions that seem to us to-day extraordinarily anomalous. There is at Charing Cross in London a large general hospital with its own eye department and next door to it there is an eye hospital; the walls of the two buildings are conterminous. There is in Maidstone at one end of a short street a general hospital and at the other end a hospital for the diseases of the eye, nose, and ear. These seemingly anomalous conditions are explained by the natural idea of the founders of the later special hospitals to provide for new wants, as near as might be to the older foundations, which formed as it were a focus of medical work in their own and the public eye.

In later days there was indeed some spirit of rivalry in the formation of further special hospitals. General hospitals recognised the necessity for special departments in their own organisation, and these with the increasing number of new special hospitals engendered a competition for patients which was not altogether healthy in that it led to abuse of hospital facilities. Those conditions are less evident now. New hospitals are not easy to form, the tendency is to improve and expand existing institutions, but there is still some sign of excessive specialisation, especially, under the pressure of social reformers, in the provision of special clinics under statutory authority—e.g., tuberculosis dispensaries, &c.

The Acid Test of Efficiency.

The determination of the relative value of special and general hospitals must be based upon their working efficiency in regard to the patient. Which type of hospital is best for the patient, whatever be the nature of his ailment; and which in the long run fosters the best type of medical practitioner—that is to say, the practitioner most able to cope with the disability of the patient.

My answer to these questions may be given now, so that there may be no doubt in the mind of the reader as to the trend of the argument. In my judgment there can be no doubt that the general hospital is better than the special hospital, better for the patient, and better in that it cultivates a superior type of medical work.

The human body must always be considered as a whole if the medical practitioner is to minister successfully to its needs. The members of the body cannot and must not be considered as detached units. Modern medicine reaffirms and proves the Pauline dictum, "all the members of the body, being many, are one body." A defective eye may react upon the whole body or the defect of the eye may be a reaction brought about by a general bodily ailment. And so it is with disease of any other of our special organs. To limit the diagnosis to the "eye," the "nose," or whatever may be the organ under examination, is to limit the power of curative medicine and the prospects of the patient. Work in a special hospital tends to be limited, bounded as it were by a ring fence. It is a natural effect of a limiting name. That this tendency is being resisted there is ample evidence, and some of this evidence will be noted later. On the other hand, in a general hospital there is a constant recognition of the full field of medical work. There is daily contact between the general physician and surgeon, the eye surgeon, the gynæcologist, the dental surgeon, and so forth. Each of these gives to the other a daily hint of his field of work, and with that there is an unconscious widening of outlook for each member of the staff, so that no matter to what department a patient may be drafted after the preliminary examination the chief of that department is always conscious of the whole anatomy of his patient. The physician or surgeon of a department recognises that he is one of a team, every member of which is at his service in elucidating the primary origin of the disease under investigation, and through such combination there is laid the foundation of ever-widening extensions of preventive medicine.

Recent Tendencies.

The advantage of the general hospital plan of work is demonstrated by recent developments of special hospitals. It is rare now to find in a special hospital the members of the staff limited to practitioners of that speciality. On the staff of an eye hospital there will be found neurologists, aurists, and even dental surgeons. On the staff of a nerve hospital there will be found eye surgeons, aurists, gynæcologists, orthopædic surgeons, and so forth. On the staff of a lying-in hospital will be found physicians and surgeons, a physician for antenatal work, another for infant consultations, and also ophthalmic and dental surgeons. Such a range of staffing in special hospitals is proof of the desire for a wide outlook and comprehensive team work; in fact, it is an attempt to make the work of the special hospital as near akin to that of a special department in a general hospital as is possible. Again, in recent years there have been amalgamations and close associations formed between general and special hospitals whereby the special hospital has become an integral part or department of the greater general hospital.

It may be asked: Is there no countervailing advantage in the special hospital—e.g., in the intensive cultivation of one branch of work in one place? There is such an advantage. Doctors are as gregarious as other human workers. It is of interest to us to work together, especially when we are doing the same work. Minds are stimulated, ideas are kindled, and on occasions special advances are secured. But there is a risk of one-sided growth through loss of contact with general medicine and surgery or of loss from failure to know what other branches of medicine are doing. Special hospitals are not the sole means whereby we specialists intercommunicate. We have our special medical societies, our sections in the greater medical societies, and our clinical meetings in hospitals.

The Rule and Exceptions.

My conclusion is that a general hospital with a range of departments covering all modern requirements is the ideal unit of hospital organisation. It provides the maximum of benefit with the minimum of risk. But that does not mean that special hospitals should cease to exist. In a great city special hospitals may be of convenience in dealing with large numbers of patients of a presumably distinctive type, also for concentrating special research and teaching in universities. There may be limitation in the ground space available for a central general hospital, so that outlying clinics attached to the central hospital may be more economical, and if these are annexes of the central organism the disadvantages of excessive specialisation are reduced. Again, certain kinds of disease need long periods of treatment, and treatment in the country rather than in the towns—e.g., orthopædic cases and tuberculosis. Other disease might present danger or inconvenience in the general hospitals —e.g., specific fevers and mental disease. Safety and convenience make for separate accommodation in these cases. But there is no physician who will not agree that so far as fevers are concerned separation is a matter of convenience only and not an ideal medical arrangement. Whilst in the case of mental diseases the evidence given before the Royal Commission now sitting is conclusive that the ideal for mental cases is treatment in association with general hospitals. Something more than convenience justifies children's hospitals; they are, in fact, general hospitals for children, their smaller size makes them better units for the little ones; but even with these hospitals there are occasional difficulties in dealing with the older children, and in finance because of the relatively high cost of laboratory and physical equipments in small hospitals; both these difficulties make an association with the larger general hospital desirable. The treatment of disease of the nervous system and of orthopædic cases is commonly of such long duration and requires such complicated and special equipment that there is a real justification for separate provision. But there is no such justification for separate hospitals for disease of the eye, nose, ear, throat, skin, heart, rectum, urinary organs, for cancer cases, nor for radiological treatment. All these are better provided for in, or at least in association with, the unit of hospital organisation, the general hospital.

* Appendix to the Sixth Annual Report of the Voluntary Hospitals in Great Britain (excluding London).

British and American Opinion.

So far as my information goes, this is the trend of opinion within the British medical profession both amongst men in general and in consulting practice. It is also the expressed opinion of the most recent writers on American hospitals, where the English system of voluntary initiative is dominant. Corwin[1] in a survey of the hospital situation in Greater New York writes: "The fact that so large a percentage of hospital beds in the City is to be found in the special hospitals (about 37 per cent.) raises the question of the desirability of such development." He concludes, "It is safe to say that in the City of New York in the development of special institutions the zenith has been reached, and that hospital development in the future will probably proceed along lines of greater scope on the part of general hospitals."

The situation in this country calls for the direction of wise statesmanship. The British Medical Association[2] after consideration of this matter has urged that the local voluntary committees, now existing, should be expanded so as to enable them to survey all the hospital accommodation of their areas, to determine the adequacy of this accommodation, to foster coördination between existing special and general voluntary hospitals and municipal and Poor-law institutions for the treatment of the sick; and to do so without interfering with the domestic autonomy of the several hospitals, each being encouraged to work upon those lines of local initiative which have proved so vital in local work. Further, that the duties of the Voluntary Hospitals Commission should be extended so as to make it a Standing Consultative Hospitals Committee for England and Wales, representative of all the local voluntary hospitals committees, and to act as between the Ministry of Health and the local committees in all matters concerning the hospital policy of the Ministry.

The time is ripe for a move in this direction, and it is better that such a move should come from within the hospitals rather than from without.

THE IDEALS OF SOCIAL HYGIENE.

SPEAKING at King's College on Oct. 8th on biology and social hygiene, Prof. Arthur Thomson said that the contrast between civilised society and wild nature is in many ways disquieting. Among mankind constitutional disease is rife, whereas in wild nature it is rare. Nature is all for health, whilst to man health is often secondary. Nature is always sifting for health, but civilised society shelters cobbles and coddles. The lamentable exhibition of the pathology of sex amongst men is due partly to repressions and suppressions, partly to mental materialisation, and partly to the departure from the old method of preferential mating. Amongst animals sex pathology is rare. In a plea for clear thinking, Prof. Thomson condemned "the fallacy that the endocrine glands determine the personality in ordinary men and women." The healthy body without the healthy mind is only half way to happiness. There is need for a freshened enthusiasm for health and incidentally for beauty. Prof. Thomson suggested ways of promoting such enthusiasm, but insisted that social organisation and ideals must be improved. "We are enmeshed," he said, "in a net of social traditions and trammels handed on from the early industrial or palæotechnic age." Wealth without health is vanity.

The lecture was the first of a series to be held on Thursdays, at 5.30 P.M., at King's College under the auspices of the British Social Hygiene Council. The subject of the course is the Ideals of Social Hygiene, and the lecturers will include Prof. Cyril Burt, Dr. Malinowski, Prof. Percy Nunn, Prof. Winifred Cullis, and Sir Arthur Newsholme.

THE FOULING OF FOOTWAYS BY DOGS.

To the Editor of THE LANCET.

SIR,—I am glad to see from your annotations that you are taking notice of the fouling of the pavements by dogs in Kensington. I have felt very strongly in the matter and went to the M.O.H. for Kensington about it, and I think it was on my suggestion that a notice on the subject was inserted in the tax-note for dogs, but I wish I could feel that any real good has so far been done. The pavements are as foul as ever. I do not think any good will be done until the police can be persuaded to deal with the nuisance, and perhaps your powerful words may help them. I do not think that the traffic can have anything to do with the case. It is a matter for the owners of dogs, who do not take the trouble to train them properly. Why Kensington should be the only borough to take the matter up I do not know. The need for remedy is obvious in all big towns.

I am, Sir, yours faithfully,
WALTER RIGDEN.

West Bolton-gardens, S.W., Oct. 11th, 1925.

A LOCAL PUBLIC HEALTH GUIDE.

THE medical officer of health of St. Pancras, Dr. G. Sowden, has compiled for the use of the medical practitioners in the borough an extremely useful booklet of information. This booklet was circulated during Health Week. It is of handy size for the pocket and contains about 13 pages of printed matter, showing in alphabetical order not only the various public health activities of the borough council, but also information with regard to ambulances, voluntary hospitals, and voluntary societies of all kinds. The function of the maternity and child welfare centres is explained in detail, in order to remove any misconceptions that may exist. The duties of medical practitioners with regard to notifiable diseases, including those notifiable under the Factories and Workshops Acts, are given. The work of the tuberculosis dispensary is explained and the facilities provided with regard to special schools and school clinics, &c., are enumerated. We think the booklet will prove very valuable, especially to those practitioners who have recently begun to practise in the borough. The idea seems well worthy of imitation in other districts.

Messrs. L. G. Coade and Co., electrical engineers, of 55, Temple-row, Birmingham, invite medical men to inspect various models of the K.B.B. ultra-violet lamps for medical therapy.

Mr. John C. Carr (Registered Dentist, 1922) writes that after abundant opportunity of observing the various methods of anæsthetic administration by dentists in America and this country, he is satisfied that gas and oxygen is the one and only general anæsthetic that should be used in the extraction of teeth. But however secure the dentist may feel of his anæsthetic and of his skill as anæsthetist, in any case of doubt as to the presence of existing disease or debility a dental operation should be postponed until the patient has been referred to his medical adviser for examination. In dealing with male patients Mr. Carr's practice is, generally speaking, to give a local anæsthetic and extract only a limited number of teeth at one sitting. Should a general anæsthetic be insisted upon, the physical condition being equal to it, gas and oxygen is given. In women he regards gas and oxygen as perfectly safe, even during pregnancy. He uses the combined apparatus of Hewitt and Weller, the valve being controlled by the left hand.

The Harveian Oration

ON SOME DEVELOPMENTS OF HARVEY'S DOCTRINE

"OMNE VIVUM EX OVO."

Delivered before the Royal College of Physicians of London on Oct. 19th

By Sir FREDERICK MOTT, K.B.E., M.D.,
F.R.C.P. Lond., F.R.S., LL.D. Edin.,

CONSULTING PHYSICIAN, CHARING CROSS HOSPITAL; LATE DIRECTOR OF PATHOLOGICAL LABORATORIES, LONDON COUNTY MENTAL HOSPITALS; HON. DIRECTOR OF RESEARCH IN MENTAL DISEASES TO THE UNIVERSITY AND CORPORATION OF THE CITY OF BIRMINGHAM.

[After referring to the greatness of Harvey as an investigator and to the value of his "De Generatione Animalium," Sir Frederick Mott described the growth of the knowledge of genetics since that work was published. The expansion of Harvey's dictum, *Omne vivum ex ovo* into Virchow's *Omnis cellula e cellula* had opened up a new chapter in physiology and pathology and the investigations which followed had thrown new light on the conceptions of fertilisation. The reviviscence of Mendel's great discovery (1865) of segregation of unit characters had awakened in 1900 an interest in the chromosome theory of heredity, and Sir Frederick Mott gave a brief summary of this theory, in so far as it applied to his subject. Turning to his own research into the function of reproduction and genetics in relation to certain mental diseases, he continued :]

From time immemorial the influence of the sexual function on physical structure, character, and conduct has been known, but it is only within recent times that experimental investigations and clinico-anatomical observations have shown that this influence is dependent upon an internal secretion of an interstitial gland of the testis and ovary respectively, which can function independently of the genetic structure. The testis secretes a hormone which determines, prior to birth, the physical and mental sexual characters, and, at puberty, the secondary sexual characters. The reproductive organs are functionally correlated with the endocrine system of glands, especially the cortex adrenalis, the pituitary, and the thyroid. As the sex instinct gradually matures, a progressive mental and bodily evolution takes place in the male and female, in accordance, not only with the innate dispositions due to sex, race, and familial ancestry, but with the evolution of character due to good or bad habit formations. Habits acquired in early life, although not germinal and transmissible, nevertheless form such stable organised reflex patterns in the nervous system as to be capable of profoundly influencing such inborn dispositions as the moral sense, the self-regarding sentiments, the emotions and passions, and their proper control. At the adolescent period a new great vital urge, stronger even than self-preservation, comes into being to energise all the organs and tissues of the body, especially the nervous system, for the supreme biological end of reproduction and preservation of the species.

The Interstitial Cells of the Testis.

I will now give a short account of my own investigations regarding the interstitial cells in man and their functions. Examination of the testis of a full-term twin fœtus showed tubules containing embryonic spermatogenic cells; between them, lying in loose connective tissue, were seen abundant polygonal cells with a round nucleus lying in an eosin-stained cytoplasm. Many of the cells had the appearance of young cells. There was plenty of evidence of nuclear mitosis, and I came to the conclusion that numbers of the cells had attained maturity and were on the way to a regressive atrophy, leaving only the nuclei. These cells contain a lipochrome substance and lipoid granules. I found that about the fourth month the seminiferous tubules are twice the size of those at birth; instead of being separated by loose connective tissue containing abundant Leydig cells, they are closely approximated, the Leydig cells have almost disappeared, and there are no lipoid granules visible. At the eleventh year I observed very little change in the size of the tubules and the interstitial cells are only discernible by examination with an oil immersion lens. Little or no interstitial lipoid is seen. There are commencing manifestations of nuclear activity and karyokinetic figures, but no spermatids nor spermatozoa. The Leydig cells do not reappear until puberty, when the generative function commences, and the sexual hormone from the interstitial cells begins again to pass into the circulation and determine the bodily and mental secondary sexual characters.

Seeing that the male sexual hormones are active for probably more than six months in prenatal and postnatal periods, it follows that this influence must have been operating on all the somatic cells, including the nervous system, during all that time. If there be an elective storage of the sexual hormone in the nervous system, as Steinach's experiments indicate, then a masculine behaviouristic tendency may thus early be engraven upon the nervous system. Moreover, by the sensitising influence of the testicular hormone, the primary male characters are thus early in life made dominant in all the bisexual somatic cells. The belief in the occurrence of male sex-dominance at an earlier age than the existence of a secretion of the female sex hormone has received fresh support in the very interesting solution of the riddle of the "free martin" by Lillie. He reports a case in which the female characters of a female twin calf were more or less completely suppressed and certain male structures developed as a result of anastomosis of the placental blood-vessels with those of the associated male twin calf. This can only be explained by the influence of a soluble and diffusible hormone derived from the male and carried to the female by the circulating blood. We can thus understand why castration, even in early life, cannot remove entirely the hormonic effect thus early impressed upon the nervous system, nor eliminate entirely the physical primary male sexual characters already determined in the tissues.

Other Endocrine Influence.

There can be no development of sex characters without all the other organs of internal secretion participating; all of the ductless glands, and especially the thyroid, the pituitary, and the adrenal, are influenced by the internal secretion of the sexual glands, and the latter are undoubtedly influenced by the former; indeed, there is a harmonious functional interrelation between the reproductive organs and the whole endocrine system. I have recently investigated a case of dystrophia adiposo genitalis affecting an epileptic imbecile, aged 29 at death. There was no hair on the face; there was polyuria and marked sugar tolerance; there was infantilism of the external genitals; the atrophous undescended testes were no larger than peas and showed microscopically both interstitial cells and spermatogenic cells replaced by fibrous tissue and fibroblasts. Associated with this testicular atrophy was a markedly atrophous pituitary and atrophous thyroid gland; moreover, the cortex adrenalis was much diminished in thickness.

The increase in growth of the long bones of youths castrated in early life is due to retardation of endochondral ossification, and supports the view that the internal secretion of the testis controls calcium metabolism. Similarly in the female there is a relation between the ovarian internal secretion and calcium metabolism, for removal of the ovaries benefits and sometimes cures osteomalacia. Again, the release of calcium from the pelvic bones during pregnancy and parturition may be regarded as a physiological process brought about by an internal secretion of the ovary, the phosphate of lime thus released being utilised by the mammary gland. It is generally assumed that the source of the sexual hormone of the female is connected with the development of the Graafian follicle, and that the cells of the zona granulosa and the internal thecal cells of the follicle secrete a specific soluble substance which passes into the blood and determines the female characters. It may, therefore, be supposed that a continuous conversion of primordial follicles into immature Graafian follicles, from earliest infancy onwards, provides a feminising hormone to counteract the pre-established male dominance in the bisexual cells of the body. This formation of atretic follicles, and subsequently corpora atretica, continues until menstruation occurs and maturation with dehiscence of the follicles takes place. I have found that ovaries at birth and in early infancy contain numerous immature Graafian follicles. Should this follicle formation not occur to a normal physiological extent, it is conceivable that, having regard to the selective action of the hormone on the central nervous system, as revealed by Steinach's experiments, there would be a tendency to masculinisation, especially revealed in mental qualities. The whole of the somatic cells of male and female are, until the dawn of adolescence, engaged in growth and self-preservation, in preparation for reproduction and preservation of the species.

Disorders and diseases of the mind have long been associated with two conditions—namely, heredity and the critical periods of life (adolescence, when the sex instinct matures, and the climacterium, when the sex instinct wanes). These are physiological conditions. Pregnancy, parturition, and lactation in the female are likewise physiological conditions. Two distinguished Harveian orators, the late Dr. J. A. Ormerod and Sir Bryan Donkin, have dealt with the subject of heredity in relation respectively to nervous diseases and criminology, based upon wide experience, but neither of these has treated of the relation of heredity to insanity based upon the study of pedigrees, statistical data, and pathological findings.

Mental Disease without Exogenous Cause.

There are three conditions which prove my argument that there are certain types of mental disease in which the naked-eye appearances of the brain do not afford any indication of an exogenous cause of the disorder and loss of mind presented by the symptoms during life. They are termed respectively dementia præcox, manic-depressive insanity, and involutional melancholia, of which the two latter may terminate in dementia. Through the study of a large number of carefully constructed pedigrees by myself and co-workers, extending in many instances to four or five generations, and of statistics based on a card system extending to 4000 related individuals who have been or were at the time in one of the ten London County asylums, I have come to the conclusion that there is a signal tendency to *antedating* in respect to these types of insanity. That is to say, if a parent suffered with manic-depressive insanity, or a parent or grandparent with involutional melancholia or senile dementia, one or more of the descendants may suffer during adolescence with dementia præcox. In the construction of pedigrees I was particularly struck by the fact that two, three, or even four or five members of the same co-fraternity at about the same age suffered with mental disease—usually dementia præcox; sometimes with manic-depressive insanity; not infrequently with dementia præcox *and* imbecility. This is a more striking proof of hereditary transmission than when a mental disease is transmitted in successive generations.

When there is evidence of insanity or epilepsy in both stocks, or a general neuropathic tendency indicative of mental instability, the liability to dementia præcox is greatly increased in the descendants; therefore in advising (as one often has to do) in regard to marriage, evidence pointing to these special forms of mental disease in both stocks, on one side, still more on both sides even if shown in collaterals, induces one to say definitely from a eugenic point of view that it would be inadvisable—inasmuch as the risk of an insane inheritance for the children is so much the greater. Moreover, in some of the pedigrees it looked as if there were segregation of unit characters, for I was able to find healthy children who married and had a healthy grown-up progeny in the same co-fraternity with cases of dementia præcox and imbecility. But, as the late Dr. Ormerod and Sir Bryan Donkin pointed out in their interesting Harveian Orations, there are too many complicating factors to permit of Mendelian principles, which are so striking in animals where breeding can be controlled, specially in relation to mental diseases. I have to omit here the statistical data, but I should like to refer to one result of them, because it supports my premiss. Prior to the war the number of cases of dementia præcox admitted to asylums was about equal in the two sexes, likewise the average age incidence (about 23 years). During the war there were half as many male admissions of dementia præcox as females whose parents were or had been in the London county asylums. The age of these males averaged 17·5 instead of 23·5; the reason being that those over the age had been conscripted, and I may state that 14 per cent. of the insane in the Army were cases diagnosed as dementia præcox.

Dementia Præcox a Vital Defect.

By a comparison of the mental and bodily conditions of an acquired mental disease—general paralysis of the insane—with the mental and bodily conditions found in dementia præcox, I shall endeavour to show that dementia præcox is a vital defect of the reproductive organs, and of the brain in particular, and probably of the whole body.

Spermatogenesis.—I have investigated spermatogenesis in 108 cases dying in hospitals and asylums at different ages and in different bodily states, including normal death from shock of injury. I have found it active from puberty to old age (81) with individual variations in degree. In cases where severe chronic disease occurred in early life there has been found absence or deficiency of spermatogenesis. In adults dead of shock following accident, tuberculosis, dysentery, broncho-pneumonia, enteric fever, gangrene of lung, active spermatogenesis was found. It was absent in several cases of prolonged extensive suppuration and in several cases of cancer. But these were diseases in which an active prolonged cell proliferation had taken place.

In general paralysis local patches of atrophy of the testes with dense fibrosis occurred in many of the cases examined, but with very few exceptions, in a large number of cases, active spermatogenesis in all stages was found in spite of intercurrent disease. The atrophied patches were due either to gonorrhœal epididymitis or localised syphilitic inflammatory affection of the testes. The dense white fibrous patches microscopically examined exhibited tubules consisting of thickened basement membrane without Sertoli cells or spermatogenic cells of any kind. The atrophic process was due to a regressive atrophy, as in dementia præcox. This, moreover, was shown to be the case by the fact that normal tubules with active spermatogenesis and Leydig cells could be found in the midst of the atrophied tubules. In spite of this secondary atrophy which affects the testes of many paralytics, the average weight of the pair after removal of the epididymis and tunica vaginalis is 8 grammes heavier than the testes of dementia præcox; whereas in the majority of cases of dementia præcox examined an emulsion of the testes revealed no spermatozoa, the converse was found in paralytic dementia.

In 27 cases of dementia præcox of which the testes were examined, either a commencing, a partial, or a complete primary regressive atrophy was evident by the morphological and micro-chemical changes in the spermatogenic epithelial cells and the interstitial cells, with a corresponding thickening of basement membranes and overgrowth of interstitial connective tissue. With a few exceptions these testes of dementia præcox cases showed less evidence of active spermatogenesis than the testes of an old senile case aged 81 at death. In 27 per cent. of the cases the interstitial cells showed the pigmentary degeneration found in old age.

Circulating Toxins.—I have no time to deal with the very important question of the influence upon the germ-plasm of circulating toxins in the blood. But the study of the testes of 100 cases dying of all forms of disease, and yet, except in dementia præcox and imbecility, showing with very few exceptions active spermatogenesis, appears to me to find a solution in the fact that a barrier of lipoid granules, similar in chemical composition to the lipoid granules in the cortex adrenalis, was found. These granules consist of a lecithin-cholesterin ester. The cholesterin acts as an antitoxin. Now I found in cases of microbial toxæmia that the lipoid-cholesterin ester disappears from the cortex adrenalis, and some people speak of this gland as antitoxic in function on this account. It seems to prove that Nature will provide as long as it can for the protection of the germ-plasm. There is evidence to show that these lipoid granules are connected with oxidation processes, and would therefore protect the germ-cells against poisons like alcohol circulating in the blood. Whereas in general paralysis clumps of eosin-stained cells could be seen in sections of the testes with a low-power magnification, in the great majority of cases of dementia præcox eosin-stained clumps were not visible; the appearances suggest a failure of these interstitial cells to maturate. Fibroblasts and dense fibrous tissue tend to replace the Leydig cells. It is less easy to show the regressive atrophy in the ovaries for various technical reasons, but the study of 100 patients dying in hospitals and asylums led me to the conclusion that there is, similarly to the male reproductive organ, a tendency to regressive atrophy of the reproductive organs in the female in dementia præcox, as evidenced by the deficiency of the chromatin in the nucleus of the primordial follicles, their disappearance and replacement by fibroblasts. The organ shows a sclerotic condition even in many young women suffering with this disease.

A CASE OF ACUTE DEMENTIA PRÆCOX DESCRIBED.

To the first volume of "Libro en Honor" of Ramon y Cajal I contributed a paper upon the Genetic Origin of Dementia Præcox, giving the clinical history and pathological findings in the brain and reproductive organs of a case of acute dementia præcox. The following is a summary:—

> There was a family history of insanity on both sides. A brother died in Charing Cross Hospital from a self-inflicted bullet wound of the brain. The testes were sent to me in 1916, as I had asked for the testes of cases dying of injury; pronounced regressive atrophy was found. I put them aside, after finding they were very abnormal, and forgot all about them. Five years later I was asked to see a case at Claybury Asylum of acute adolescent insanity, and I was struck by the patient's name and by the history of the brother having died from a self-inflicted bullet wound. I then recollected the name and recognised that it was that of the brother who had died in Charing Cross Hospital. There was a history of a sister who had been admitted four times to an asylum with manic-depressive insanity with sexual delusions; a brother and sister were normal; all the five were highly intelligent. The blood and cerebro-spinal fluid examined during life were both sterile; and there was only slight leucocytosis. The patient died 11 days after admission. The duration of the mental symptoms was about two months; they were characterised by depression, suicidal tendency, and delusions of persecution. He died of heart failure with cerebral congestion and œdema. The testes, freed from tunica vaginalis and epididymis, weighed only 8 g. each, which is less than half the normal weight. They presented a uniformly grey instead of a white appearance, quite like the organ in advanced cases of dementia præcox. The microscopic appearances of regressive atrophy were in all respects a counterpart of those I had found in the testes of the brother. Sections of the testis revealed tubules in all stages of primary regressive atrophy. Some of the tubules showed only a thickened basement membrane lined by Sertoli cells without any spermatogonia or spermatocytes; in others there were all stages of regressive degenerative atrophy of the spermatogenic epithelium, shown by a diminution or even absence of nuclear chromatin in spermatogonia, spermatocytes, and spermatids. Where spermatids or spermatozoa were seen there was evidence of a micro-chemical or morphological change similar to the condition I have found and described in other early cases of dementia præcox. The interstitial tissue displayed an overgrowth of fibroblasts, the cells of Leydig were diminished in size and numbers, the nuclei of the cells were deficient in chromatin, smaller than normal, irregular in shape instead of round, the cytoplasm was deficient in eosin-staining substance, and the appearance of the cells generally was that of a regressive atrophy. Pronounced nuclear and cytological changes were found in the cortical neurons generally, but the small stellate cells of Cajal were particularly affected.

The microchemical and morphological changes of the nuclear material of the cortical neurons and of the testis in this case indicate an hereditary biochemical deficiency of nuclear material in two structures essential for the preservation of the individual and the species. It has been asserted that the nuclear changes in the reproductive organs and the cortex of the brain in this disease are due to tuberculosis. In neither of these two young men was there any evidence of tuberculosis, but a strong family history of mental disease on both paternal and maternal sides.

CORRELATION OF DEMENTIA WITH PHYSICAL CHANGES.

In general paralysis the degree of dementia can be correlated with the degree of decay and degeneration of the cortex caused by the spirochætal infection and the escape of toxins into the cerebro-spinal fluid. There is a proportional extent of chronic inflammatory change, thickening and adhesion of membranes, and atrophy of the convolutions, obvious to the naked eye and sufficient to account for the loss of mind. The parallelism is shown in the fact that if there is well-marked speech defect the left hemisphere will weigh usually 20 to 40 g. less than the right. Chance is everything, hereditary disposition nothing, in this disease. There is chance of the individual being infected, but only 5 per cent. of those infected owing to colonisation of the spirochæte in the brain suffer from general paralysis. Likewise chance is everything in the juvenile form due to congenital syphilis.

In dementia præcox the macroscopic appearance of the brain exhibits nothing abnormal, and even microscopic examination shows little. How can the mental symptoms, then, be correlated with the microscopic changes found in the cortex? Before considering this matter more fully let me state what are the fundamental symptoms of dementia præcox: they are a weakening of judgment, of attention, of mental activity, of creative ability; the dulling of emotional interest; loss of energy; and, lastly, the loosening of the inner unity of psychic life. The biological view I take is that there is an inherent defect in the fertilised ovum, which shows itself in later life in two structures connected with the primal instincts of self-preservation and preservation of the species, and in those very structures where active nuclear formative processes take place—namely, the cortex cerebri and the reproductive organs. The brain does not waste in dementia præcox because the axon remains alive and the white matter surrounding the axon does not degenerate. Now the grey matter of the cortex, where all the essential chemico-physical processes take place, according to Donaldson, does not amount to more than one-fiftieth part of the white matter of the cerebrum. Yet if there is functional or structural synaptic dissociation there will result a corresponding failure of psycho-physiological processes and disintegration of the psychic unity according to the nature and degree of dissociation. Accordingly, to the naked eye, the brain may appear normal, and even microscopic investigation may not disclose in many cases (where the mental symptoms are mainly due to suspension of function) histological changes sufficient to account for the symptoms, as in manic-depressive insanity, where the patient returns to normal mentality.

Genetic Inadequacy.

How can we explain the dissociation (schizophrenia) from a physiogenic point of view? I should say by genetic inadequacy—namely, an inherent defect of the vita propria of the neurons, especially of those developed from the telencephalon. This portion of the neural tube is the latest to develop phylogenetically and ontogenetically. The countless millions and millions of neurons which constitute the cortex of the cerebral hemispheres have developed from relatively a very small portion of the original neural blastema. At birth further neuronic formation ceases, and further formative activity consists only in growth and extension of nerve-cell processes. This continues until at 2½ years the brain has attained a size nearly two-thirds of that of the adult. After this growth proceeds slowly until adolescence. There may be a varying amount of prenatal complete arrest of neuronic development, affecting especially those neurons of the highest level which are of evolutionary latest development—namely, the supragranular layer of pyramids—and various grades of amentia may be the result. There may be various degrees of partial arrest of growth and extension of the dendrons, by which there is only incomplete synaptic junction of many neurons of the highest evolutional level. Such a condition may lead to a failure in the highest level of control without much morphological evidence of a mental defect.

Lastly, there may be an inherent lack of durability of the neurons by which they are incapable of performing their functions of storage and transformation of energy during the life of the individual. In normal physiological conditions the neurons should be capable of functioning as long as the whole organism lives. Through an inherent defect they are apt to fail to function at the critical periods of life—namely, adolescence, the climacterium, and senescence; physiological conditions of stress—gestation, parturition, and lactation—may occur in the female. Again, such causes of psychological stress as emotional shock, repression and frustration of the sex instinct, causing endocrine disturbance and insomnia, are exciting causes of the onset of disordered functions of the highest level of neurons. If a deficiency of thyroid secretion can arrest structure, and thereby function, producing cretinous idiocy, it is not surprising that a deficiency of thyroxin in the blood should cause slowing of nervous function when the growth of the neurons is completed. But the thyroid gland's function is correlated with the whole reproductive endocrine system.

A noticeable histological feature in the brains I have examined of cases of dementia præcox is a morbid change in the nucleus. This change was first described by Nissl as occurring in the cortical cells. It was later described by Alzheimer and by most investigators since. It shows a swelling with often irregular infolding of the nuclear membrane, and deficiency or absence of the basophil staining of the intranuclear network by Nissl stain. In the light of recent researches on the chromosomes in relation to heredity this defect of nuclear chromatin, which occurs also in the reproductive organs, suggests a primary genetic defect. Now the nucleus of the neuron plays undoubtedly an important part in the function of transformation and discharge of energy from the cell. Although the Nissl granules are artefacts and do not exist in the living cell, yet their presence in the body of the cell and dendrons, and the microchemical reaction they give—showing that they contain phosphorus and iron—indicate that in the living neuron there is a continuous interaction between the surface of the granules and the nucleus by the mediation of the cytoplasm.

There is evidence that the granules which are contained in the body of the living neuron and its dendrons, but not in the axon, may form an oxygen surface, and that the iron of the nucleus may act as a catalase; now if there is a nuclear failure, as histological observations show, this may account for the neurons being unable to transform and discharge energy along the axon. The neuron is still able to live and its axon is not wasting, therefore the brain does not waste. How, then, can we associate this evidence pointing to a defect in the specific functions of the evolutionally latest and highest developed level of the brain with the philosophical teaching of Hughlings Jackson? The latter, in his discourse on the Factors of Insanity, points out that positive symptoms such as illusions, hallucinations, and delusions, which are so frequently met with in this disease, are evidence of functional activity brought into relief by the negative condition of the highest evolutional level.

What, then, is the original cause of this abnormal variation in the inborn vis propria of the fertilised ovum? It has been suggested that syphilitic antecedents may be the cause of dementia præcox, but I have been unable to find proof of this after examination of the cerebro-spinal fluid of a large number of cases of dementia præcox. It is a fact that these diseases do occur in primitive peoples, only the symptoms, such as hallucinations and delusions, are coloured by social usages, customs, and beliefs.

Tendencies Inborn and Acquired.

Lastly, from a practical consideration of the subject of insanity, it is very necessary to recognise that the germ-cells of every person who is certified as insane and sent to a mental hospital are not necessarily possible potential transmitters of a mental disease. General paralysis of the insane and many other microbial infections leading to disordered mental functions are acquired diseases and are not hereditary. Neither is it right to assume that simple senile decay affecting the brain is transmissible, yet a large percentage of inmates of asylums are sent there on account of senility. These legal administrative conceptions of mental disease must therefore vitiate all statistics in respect to heredity as a cause of mental diseases, because based upon data in which admissions to a mental hospital are in many instances the sole evidence.

This does not apply to the same extent to carefully recorded pedigrees; but even these are not free from error, for often all the information that can be obtained is that one or more members of the stock had been in an asylum. How is the public to know the difference between an inborn tendency to insanity *ab initio* in the ovum, true heredity, and a condition which may arise after conjugation of the male and female germs while the developing embryo is still in the body of the mother? As Sir Bryan Donkin pointed out, congenital disease was confounded with hereditary disease even by medical witnesses who gave evidence before the Royal Commission on Feeble-mindedness. The term "hereditary syphilis" is a misnomer. Much may happen while the embryo is still in utero. The normal biological processes of nutrition of the developing embryo may fail; abnormal mechanical conditions may arise in the uterus, interfering with the proper development of the embryo; or mechanical conditions in the process of development of the embryo may arise, interfering with the development of structure. Of all the structures in the body of the embryo likely to be affected by a departure from normal dynamic biological conditions of growth, the great brain or cerebrum is the most likely. The neo-encephalon—new brain—of mammals appears first as two hollow buds from the telencephalon, which by rapid cellular proliferation grow upwards and backwards to cover up completely the basal ganglia and mid-brain to form the cerebral hemispheres. In that process many mechanical failures and accidents may occur, interfering with the vascular supply or nutrition of the rapidly proliferating cells, whereby the process may be arrested altogether, as in anencephaly, or partially arrested, as in the brain of the idiot or low-grade imbecile.

There is evidence of a possible vascular cause through a lack of correspondence in the normal rate of growth of the dura mater and soft membranes and the growth of the brain. Owing to this the veins enter the longitudinal sinus in a direction opposite to the current of the blood-stream in the frontal lobes—an anatomical condition which favours venous stasis. This I have put forward as an explanation of the fact that the frontal lobes are the seat of early and most pronounced meningo-encephalitis and atrophy in paralytic dementia, because the spirochætes, being anaerobic, would develop more easily where there is venous stasis. Again, prolonged labour and difficulties in delivery requiring the use of instruments may be responsible for injury of the brain. Idiots and imbeciles occur in all grades of society (frequently they are the first-born), and it is not at all uncommon to find nothing in the paternal or maternal family history—even when a pedigree can be obtained of three or four generations—to account for this pronounced failure of development of the anatomical basis of mind. The late Dr. Henry Ashby considered that 25 per cent. of the cases of idiocy and imbecility were due to other causes than heredity.

Cameron Lectures

Delivered at the University of Edinburgh on Oct. 19th, Oct. 20th, and Oct. 22nd, 1925,

BY HARVEY CUSHING, C.B., F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN HARVARD UNIVERSITY.

LECTURE I.*—THE THIRD CIRCULATION AND ITS CHANNELS.

> " Cet enfant a de l'eau dans la tête, dit le vulgaire ; cet enfant est hydrocéphale, dit gravement le médecin, répétant littéralement par un mot grec ce que dit l'ignorant dans sa propre langue. Mais quelle est cette eau ? d'où vient elle ? Voilà ce dont les médecins auraient dû s'occuper."—*François Magendie, 1842.*

As a tribute to the memory of François Magendie, I propose to devote the first of these lectures to the subject of the cerebro-spinal fluid, for just 100 years have passed since the appearance of the earliest of his epoch-making publications in which attention was drawn to the physiological importance of the peculiar watery medium which bathes the central nervous system.

Something of the state of our knowledge before Magendie's time may be gathered from a paper (1768) on Dropsy in the Brain by the celebrated Robert Whytt, one-time professor of medicine in this university, wherein is given the first recognisable description of what must certainly be tuberculous meningitis.

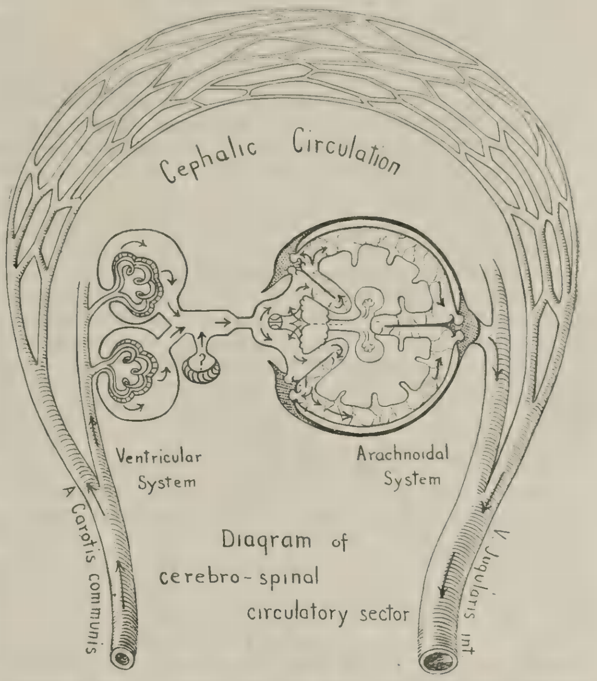
> " The immediate cause of this disease," he says, " and indeed of every kind of dropsy, is always the same—viz., such a state of the parts as makes the exhalant arteries throw out a greater quantity of fluids than the absorbent veins can take up."

But Whytt, though a man ahead of his time, could have had no possible conception that the cerebro-spinal liquor was a specialised medium with a peculiar circulation of its own. And as my chosen title indicates, it is this particular feature of the fluid—namely, its circulating character—that I wish to emphasise, and I shall have less to say about its biochemical and cytological characteristics in health and disease, so thoroughly studied by many, than about the channels through which it percolates.

THE FLUID AND ITS CONFINES.

On Movement in a Circle.—It is quite evident that Magendie, who believed the fluid was secreted by the pia, much, for example, as pericardial fluid is secreted, had no idea of its movement as other than an ebb and flow. And this truly Galenic conception of a cerebro-spinal fluid circulation still holds in most modern text-books of physiology, even though Key and Retzius gave a hint of the actual state of affairs by demonstrating the continuity of the fluid-holding leptomeninges as distinct from the subdural space, and by suggesting (without satisfactory proofs, to be sure) that the granulations of Pacchioni represent portals through which the fluid passes from the arachnoidea into the large meningeal sinuses. . . .

FIG 1.



On the whole, it would appear medical students get little information about the fluid as a circulating medium in their course in physiology, and what they get is mostly wrong.

This curious neglect of a vascular system which teems with biophysical problems can only be explained on the grounds that the subject of intracranial dynamics is one of the few on which Carl Ludwig, the father of modern physiology, did not focus his fertile mind, and his pupils unto the third generation have followed suit. . . .

That the arterial and venous blood has " a motion as it were in a circle," in contradistinction to the Galenic idea of an ebb and flow, was the conception, when put to proof, by which the immortal Harvey transformed medicine. For even though the idea, from the heart around and back to the heart, was not entirely new, at least so far as the lesser pulmonary circulation is concerned, it was a view against all authority, and in the case of Servetus was burned with its author at the stake.

But the existence of another fluid besides blood which " circulated " was soon suggested by Aselli's discovery of the lacteals, and Picquet's of the thoracic duct; and finally William Hunter, or was it again your Monro secundus, who first postulated that the lymphatics represented a system of absorbent vessels which were supposed to conduct the watery constituents of the tissues ? To be sure, the movement of the chyle and lymph, under this conception, is not actually in a circle in a strictly Harveian sense, but rather in what one might describe as across a sector of the blood circle. And the same is true of the cerebro-spinal fluid which proves to be in continual movement, in a definite direction, through a highly specialised pathway, that cuts across the blood circle to envelop an organ in which a lymphatic apparatus of the usual type does not exist (Fig. 1).

---

* Lectures II. and III. will appear in subsequent issues of THE LANCET. They are slightly abridged for issue in our columns, and will be published shortly as a small volume, dedicated to a group of young collaborators.—ED. L.

In Explanation of Hydrocephalus.—Though these matters which concern the brain en masse may have failed to intrigue the attention of physiologists, they have been, if anything, of even greater interest and concern to the neurosurgeon than the localisation of function, since the success or failure of many of his undertakings depends more upon his familiarity with the fluid circulation and its possibilities as a complicating factor in his procedures than upon any other one thing. For the fluid, indeed, may prove his most stubborn enemy or his most valued ally. . . .

My own interest in the dynamics of the intracranial chamber was first aroused while engaged 25 years ago in the Hallerianum in Berne on a problem suggested by the late Theodor Kocher, who was preparing a monograph on cerebral compression for Nothnagel's "Specielle Pathologie" (1901), wherein he laid far more stress on the results of my researches during that happy year than they perhaps deserved.

On my return to Baltimore, with the intention of specialising in the surgery of the nervous system, among the first of my patients—as will probably have been true of most young men entering this particular field—were infants with what is known as essential hydrocephalus, for which a greater number of treatments have as yet been advocated than successes recorded ; indeed, if there are any clear-cut successes recorded. I had only the vaguest possible ideas of the cerebro-spinal pathways ; and if Leonard Hill's statement, made in the course of his admirable Hunterian lectures in 1896 were true—" That no pathological increase of cerebral tension can be transmitted to the cerebro-spinal fluid, because the fluid can never be retained in the meningeal spaces at a tension higher than the cerebral veins "—I could not understand how it was that a fluid which acted chiefly as a water-bed for the brain could give surgeons so much trouble, and so determined to find out something more about it if that were possible.

One of my early co-workers in the Hunterian Laboratory in Baltimore, Dr. Lewis L. Reford, undertook to study the development of the leptomeninges by injecting India ink under light pressure into the spinal canal and into the spinal subarachnoid spaces of living pig embryos of various ages. After the tissues had been "cleared" so that the course of the injection-mass could be observed, it was found that in the younger embryos fluid introduced into the canal passed headwards into the ventricles from which there was no escape ; that later on, whether injected into the canal or into the subarachnoid space, the mass would spread from the region of the fourth ventricle around the base of the brain ; and, finally, that in older pigs it would extend up over the hemispheres in what appeared to be developing meningeal spaces which had no connexion with the extracranial lymphatics. . . .

With this small beginning, and without any definite sequence, a variety of studies were undertaken during the next few years, which were merely along by-paths to the actual goal we continued to bear in mind—namely, furtherance of our knowledge of the mechanism of hydrocephalus, of which there probably were many kinds. Numerous examples of this most distressing condition in infants had meanwhile come under observation in the clinic, and it was found that in most of them the fluid could be withdrawn from the ventricles by lumbar puncture. Moreover, when a needle attached to a manometer was inserted through the bulging fontanelle into the ventricle and another in the lumbar sac, the pressure level of the fluids in both usually remained the same and fluctuated equally with crying, straining, or jugular pressure, as well as on the withdrawal of fluid from either end of the system. At the same time we observed, as many others doubtless have done, that even though large amounts of fluid might be withdrawn—as much as a completely collapsed fontanelle would permit, and amounting at times to over 300 c.cm.—within 24 hours the fluid would have reaccumulated, albeit with slightly altered chemical and cellular characteristics, and perhaps with slightly increased tension.

From these simple clinical tests I became convinced that some fault of development in the portals of outflow for the fluid from the meningeal spaces, or their occlusion by disease, was more likely to be the cause of hydrocephalus in infants than either an acquired obstruction to the passage of fluid from ventricles to the subarachnoid spaces, or a "block" somewhere in the course of these mesh-like though abundant channels. . . .

As we knew nothing at this time about the portals of drainage other than that Key and Retzius had associated them in some way with the Pacchionian bodies, structures not demonstrable in infants, and being then under the impression that some of the fluid, as maintained by many, normally escapes into the extracranial and extraspinal lymphatics which might therefore be utilised as pathways for absorption, the attempt was made to drain the subarachnoid lumbar fluid directly into the retroperitoneal tissues through a trephine opening in the body of the fifth lumbar vertebra. It was thought that this loose tissue in direct proximity to the thoracic duct would be a medium more favourable for permanent drainage than the subaponeurotic layer of the scalp which had been previously utilised for the purpose with disappointing results. . . .

Baffled in this, which proved to be a futile procedure, and believing that somehow or other in curing hydrocephalus the fluid must be allowed to get directly into the venous circulation, attempts were made to accomplish this by Dr. R. D. McClure who, as an improvement on the method of Payr, essayed to transplant a vein between the subdural space and a vessel in the neck ; and by myself, with the placement of a specially devised silver tube which led from the dilated third ventricle through the corpus callosum directly into the longitudinal sinus. As in most other surgical experiences with "essential" hydrocephalus the results were inconclusive, but the observations at least taught us that no blood subsequently passed from the sinus into the ventricle, which was regarded as an indication that the tension of the fluid must at all times be greater than that in the veins.

Filling Gaps in our Knowledge.—These early endeavours all tended to show how imperfect was our knowledge of the source or sources of fluid supply, and of the method whereby it was absorbed. In other words, too much attention had been paid to the bath itself and too little to the tap, to the construction of the tub as a container of the bath, and to the place and mechanism of its outlet. Accordingly, on my transfer to Boston in 1912, Dr. Lewis H. Weed and I set ourselves to these problems, and the following questions for which we needed answers were gradually formulated.

> Granting that the choroid plexuses are the chief source of the cerebro-spinal fluid—and this has not been conclusively proved—is the process, as some believe, a transsudation, or a secretion, or as Mestrezat regards it, a mere dialyzation from the blood ? What conditions activate and what conditions inhibit these choroidal glands ? Have they an internal as well as an external secretion ? To what primary diseases are they subject ? How early in embryonal life do they secrete ? Why does the fluid which they elaborate differ so greatly from that secreted by most other glands ? Why are the cells so impermeable to the passage from the blood-stream of drugs and of substances such as the bile pigments, which in conditions of jaundice quickly stain all other body tissues and fluids.

> Granting that the fluid thus secreted by the choroid plexuses leave the ventricles and spreads over the brain and down the cord in the subarachnoid spaces, does it receive accessions from elsewhere, from the ependyma or from pituitary or pineal glands ? Are there lymph channels in the brain, and if not, how does the central nervous system dispose of its products of tissue waste ? If there are [anything comparable to] cerebral lymphatics do they discharge into the subarachnoid spaces, and is the subarachnoid fluid therefore of the same character chemically, physically, and

cytologically as the ventricular fluid? Why normally is the fluid practically limited to the subarachnoid spaces, and under what conditions does it become subdural?

Granting that fluid may escape by way of the Pacchionian granulations, is this the chief or only manner of escape? If an important avenue, why are these structures lacking in the lower animals and in the human infant? Are these granulations, therefore, pathological processes, and, if so, what are their precursors? Are there other means of fluid absorption along the nerves by way of the lymphatics, and, if so, how important are they? How do the spaces in the pia-arachnoid develop, and do the choroidal glands mature and secrete before or after their formation? Are there faults of development at these meningeal outlets for fluid which can account for congenital hydrocephalus and for malformations such as spina bifida and cephalocele? Are there analogies in the fluid circulation of the eye to which we may attribute the disturbances of circulation of the intra-ocular fluids?

It so happened that we came to attack these questions in reverse order, "upstream" as it were; and instead of beginning with the plexus, though this was not wholly neglected, attention was first paid to the portals of exit. Dr. Weed soon hit upon a satisfactory method of identifying these structures, which was free from the objections raised against those employed by his predecessors. This consisted of a long-continued subarachnoid injection in the living animal, of potassium ferrocyanide and iron ammonium citrate in isotonic solution, under a pressure but slightly above the normal, with the subsequent immediate fixation of the tissues in an acid medium. This procedure, which served to precipitate Prussian-blue granules out of the foreign salts introduced in solution, made it possible to utilise histological methods to identify the situation of the granules in the tissues and tissue spaces.

To shorten a long story, it was found that the fluid had passed through the mesothelial cells which cap the arachnoid villi that project in large numbers through the dura into its many venous sinuses, large and small, in all parts of the cranial chamber. This, broadly speaking, was confirmatory of the view of Key and Retzius, but it substituted these innumerable and widely disposed microscopic structures for the Pacchionian granulations to which they had ascribed the function of drainage, and which merely represent pathological enlargements of some few of the villi. . . . With this substitution of countless microscopic arachnoidal villi for the occasional Pacchionian granulation as the essential portals of escape for the fluid, our conception of the process of absorption was greatly clarified; and Weed's subsequent demonstration of the ease and certainty with which a chronic hydrocephalus of high grade may be experimentally produced by the simple injection into the subarachnoid channels of lamp-black, which serves to occlude the arachnoid villi, would seem to make it most probable that damage or imperfect development of these structures is the most common cause of otherwise unexplained cases of early or congenital hydrocephalus.

The Perivascular Channels.—But to return to the views of others in regard to the process of absorption. In a study of the brains of animals subjected to experimental anæmia, Frederick W. Mott had observed that the perivascular "lymphatics" of Robin (better known to pathologists as the Virchow-Robin spaces), which represent prolongations of the leptomeninges around the vessels that dip into the brain substance, were particularly well shown (Fig. 2). These observations led him to conclude that absorption of the fluid from the subarachnoid spaces normally took place by way of these "lymph" channels with the natural corollary that the cerebral capillaries represented the chief absorbent vessels. This same view, if I read him aright, came to be held by E. F. Goldmann and is set forth in his classical monograph (1913) on vital staining of the central nervous system.

It may be assumed that both pathologist and anatomist are talking of the same thing when the one mentions the perivascular spaces of Virchow and of Robin, and the other the space of His. However, all three of these distinguished investigators originally gave such casual descriptions of the spaces in question that it is surprising that they should have become eponymic. . . . One might naturally suppose, since the superficial vessels of the brain and cord lie within the subarachnoid space, that they would carry down with them only a sleeve of pia, but as a matter of fact the so-called pial vessels of the surface, like the trabeculæ within the subarachnoid spaces, are, as Weed has clearly shown, covered by an endothelial lining. Hence, the perivascular sleeve is necessarily a double one, and there can be no question but that the space enclosed, whatever its function, lies in direct communication with the subarachnoid spaces; nor can there be any doubt as to its having a "visceral" (vascular) lining of arachnoid and a "parietal" (nervous) lining of pia rather than that, as generally conceived, it is formed by a sleeve of the pia alone which lies adjacent to the limitans glia.

FIG. 2.

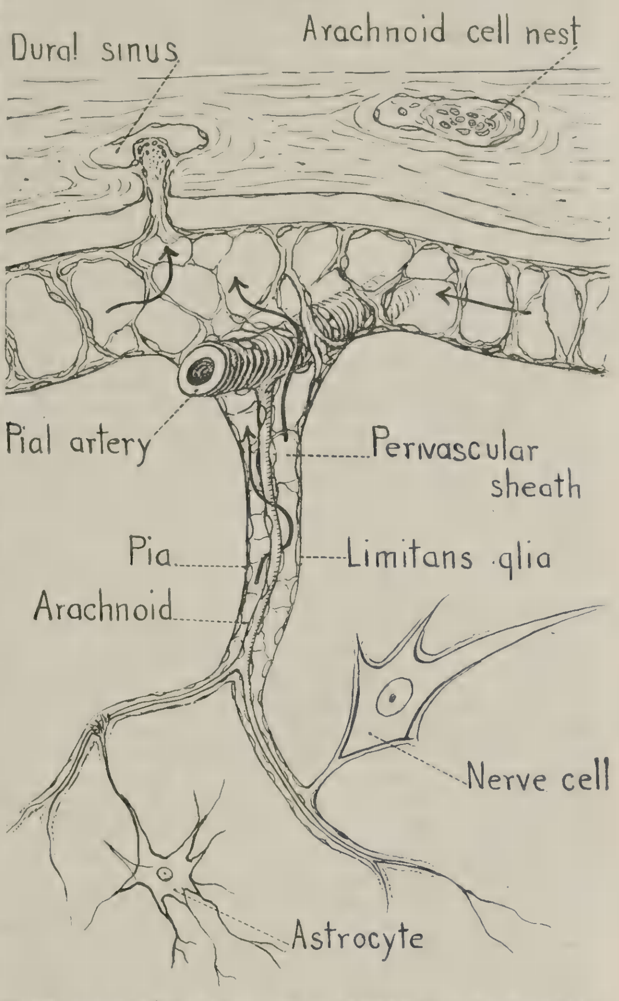


Diagram to show the sleeve of pia-arachnoid constituting the perivascular space surrounding a branch of a pial artery (modified from Weed).

But to return to our personal story. Under the condition of Weed's earliest experiments, no deposit of Prussian-blue granules was found in these perivascular spaces unless the animal were bled during the course of the injection. However, our interpretation of these facts was contrary to Mott's, for to us it seemed more probable that the normal flow in these channels should be from the brain towards the subarachnoid spaces rather than the reverse as he had assumed; and it was even then beginning to be known that these perivascular spaces become packed with cells in many disorders affecting the brain, which accounts for the early pleocytosis in the fluid.

Light on the Monro-Kellie Doctrine.—In further explanation of the direction of flow in these perivascular spaces, we must revert to the doctrine first formulated by your Monro secundus, but properly known as the Monro-Kellie doctrine, since it was further elaborated some years later by another Scotsman, Dr. George Kellie, of Leith. According to this doctrine, which introduces certain principles of physics relative to the flow of fluids through an incompressible retainer, the contents of the intracranial chamber with its three elements, nervous tissue, blood, and fluid, must always remain the same in bulk. Any increase in blood volume, for example, can only take place at the expense of one of the other elements, and conversely a diminished blood volume must be compensated either by an expansion of the brain or by an increase of cerebro-spinal fluid which probably amounts to the same thing. Hence, if an animal is bled and the brain in consequence shrinks in size, it becomes, as Weed termed it, a "thirsty brain," and the additional fluid which must necessarily be provided to compensate for the shrinking becomes sucked down into the perivascular channels.

Moreover, since these changes all take place rapidly—a matter of minutes—it is hardly possible that the great increase of fluid which the process entails could be the result of mere transudation. George Kellie was close to the facts a century ago when he said, in speaking of the effect of cerebral anæmia, that "watery effusion within the head is a pretty constant concomitant or consequence of great sanguineous depletion."

All this is part and parcel of the extraordinary phenomenon of cerebral œdema, for the brain, owing to its sponge-like structure, is apparently more capable than any other of the body tissues of taking up fluids with an enormous and rapid increase in its bulk; and it was, perhaps, through some such sequence of ideas that Dr. Weed, with his own pupils in turn, a few years later, while in charge of an experimental laboratory during the war, made the discovery that prompt changes in brain volume ensue upon the intravenous injection of hypertonic and hypotonic fluids. This discovery not only has served to provide a new method of attack on many old problems associated with the Monro-Kellie doctrine, but it has proved in the clinic to be a veritable boon for certain desperate states.

The practical applications of the discovery were obvious, and they were immediately pounced upon for therapeutic purposes. In the first place, it was apparent to the physician that drugs like salvarsan, to which the choroid plexus was impervious, might be brought more intimately in contact with the nervous tissues owing to the probable reversal of the current in the perivascular channels when the brain was shrunk by hypertonic solutions. The surgeon, on the other hand, promptly adopted the procedure as a means of lowering intracranial tension; and it is truly amazing how rapidly certain patients in deep stupor, even with Cheyne-Stokes respiration, may be brought back to consciousness after the intravenous administration of a hypertonic solution. . . .

Development of the Arachnoidea.—But I am getting far ahead of my story. Having proved to our satisfaction how it was that the fluid became absorbed, Dr. Weed on his return to Baltimore proceeded, as I have expressed it, to work "upstream," and ere long completed his extensive and now classical monograph on the development of the meningeal spaces. These spaces, as he convincingly demonstrated, are produced by a seepage through the roof of the fourth ventricle of fluid which permeates and breaks down the perimedullary mesenchymal syncytium. This occurrence practically coincides, as we had anticipated, with the development of the choroidal tufts, and supposedly therefore with the initial flow of cerebro-spinal fluid which comes to supplement the stagnant pre-existing fluid, for the undifferentiated cells of the ependyma up to this time may be assumed to have a secretory activity of some sort.

These illuminating studies of Dr. Weed's not only confirmed but greatly amplified the observations made by Reford ten years before. They serve to show with some finality: that at about the fifth week of embryonic life fluid begins to percolate through the remaining fragment of the roof plate overlying the fourth ventricle; that it finds its way through leptomeningeal channels which are thereby formed in the mesenchyme; and finally, that it escapes by way of persisting leptomeningeal communications, the villi, that project through the dura into its major venous sinuses. All of which assuredly indicates the birth of an actual circulation under the pressure of a secretion.

Meanwhile, in 1913–14 W. E. Dandy had been pursuing his ingenious studies of experimental hydrocephalus in association with Kenneth Blackfan, and though our ideas, as stated, differed from theirs in regard to the process of absorption, Dandy succeeded in making two notably crucial experiments which filled gaps in our previous knowledge. One of these was the demonstration that ventricular hydrops would occur if an inflammatory reaction were set up so as to encircle the cerebral peduncles at the level of the tentorium, which goes to show that the major course of the fluid, after its emergence from the foramina of Magendie and Luschka, is upward by way of the arachnoidea through the incisura tentorii to bathe the cerebrum.

The other of his crucial experiments relates to the actual source of the fluid concerning which, from lack of exact proof, doubts have frequently been raised. In the spring of 1911 I had had a most suggestive surgical experience with a patient[1] who had a unilateral hydrocephalus due to a cystic intraventricular tumour arising near and occluding the right foramen of Monro. After two unsuccessful efforts to give pressure relief, the ventricle, which proved to be filled with xanthrochromic clotting fluid, was opened, emptied, and the choroid plexus laid bare. From the naked plexus thus exposed, fluid could be seen to be freely exuding, but when a silver "clip" was closed on the entering choroidal artery the organ became blanched and the secretion apparently ceased. The plexus was then excised, but unhappily the patient succumbed to a subsequent attempt to remove the tumour.

In his laboratory experiments Dr. Dandy was more fortunate in his demonstration that when one foramen of Monro is occluded a unilateral hydrocephalus results, whereas if the plexus is removed coincidentally the ventricle remains collapsed. This observation could hardly leave doubt in the mind of the most sceptical that the plexus is the active spring whence the river of cerebro-spinal fluid arises, whether the actual process be one of filtration, secretion, or dialyzation. There hardly seems need of belabouring the argument further, yet Weed has recently added additional evidence by his demonstration that after the intravenous injection of hypotonic solutions, which greatly augment the amount of cerebro-spinal fluid, the choroidal cells show histological evidence of its passage into the ventricles, even though this may not be a reversible process when hypertonic solutions are injected. . . .

Hydrocephalus therefore may apparently be produced in at least three major ways: (1) by occlusion of the villi through which the fluid is normally absorbed into the sinuses (and, as a corollary, extensive sinus thrombosis, should it be compatible to life, would have the same effect); (2) by obstructions easily produced by inflammation or tumour in the narrower portions of the pathway, notably at the foramina of Monro, in the aqueduct, at the fourth ventricle, and in the narrows of the incisura tentorii; and (3) more rarely, by an increase in the amount of fluid secreted in excess of what can be cared for by the normal portals of absorption; and this is what, hypothetically, would take place could the hypotonicity of the blood, under the conditions of Weed's experiments with the injection of watery fluids, be long maintained.

---

[1] Johns Hopkins Hosp. Surg., No. 27733.

In connexion with these meningeal channels there remains to be discussed another matter, the importance of which has only been stressed of late years—namely, the physiological activity of the cells which constitute the lining of the fluid pathway. Now it is a remarkable thing, if one stops to think of it, that Nature should have provided this watery fluid, which, on the general biophysical principle of diffusion, contains the salts and sugars of the blood, but practically none of its other elements. What could have been her reason for interposing in the blood-stream this peculiar circulatory switch with its choroidal barriers and impervious pia, which keeps the fluid free from practically all known substances, whether drugs or vital dyes, which may be put into the blood-stream? Unquestionably one purpose was to provide a medium for the washing out of products of metabolism—a substitute for a lymphatic apparatus if you will—for we have learned that the intraventricular and subarachnoid fluids have a slightly different chemical composition. Then, too, it seems not improbable that something may be added to the fluid in transit which may be necessary to the economy.

Vascular or lymphatic channels might well enough have served for both these purposes it would seem, and just why another medium had to be provided within spaces, which, as we shall see, are particularly intolerant of the presence of blood cells, remains unanswered. Moreover, as may be observed, there is no method whereby a collateral circulation for the cerebro-spinal fluid can be spontaneously established in cases of obstruction, and, since it passes through a very specialised pathway, it is to Nature's provisions to keep the pathway in repair and free from foreign substances which might obstruct the fluid outlets that I wish to devote the remainder of this hour.

THE CELLULAR LINING OF THE MENINGEAL PATHWAY.

The "Meningocytes" and Reparative Processes.—The mesothelial cells which line the extraventricular fluid spaces possess a most remarkable capacity for repair as must have been observed by many. I may give an example. The efforts which were made many years ago to drain the hydrocephalic ventricles by establishing a communication with the subaponeurotic layer of the scalp, in the expectation that the fluid would permanently escape into the lymphatic spaces, led to disappointments. For under these circumstances a very peculiar and striking thing happens. The scalp at first becomes widely œdematous, but in the course of a few days the œdema gradually subsides, and finally a circular pool of fluid a few centimetres in diameter is all that remains. This disc-like subaponeurotic pool, which continues in free communication with the ventricle, becomes promptly lined with a layer of glistening serosal cells, like those lining the dura, which are impervious to the further escape of fluid into the tissues.

Early in our surgical experiences with what is known as a subtemporal decompression a comparable observation was made—namely, that a new dural membrane would promptly re-form without any adhesions to the brain, provided the leptomeninges over the surface of the exposed temporal lobe were not injured in the process of opening the dura. This neo-membrane would so perfectly repair the defect over the bulging lobe that anyone who might happen after an interval to re-operate upon the patient or to conduct a post-mortem examination would be likely to doubt whether the pachymeninx had ever been opened. . . .

Practical applications have been made of this extraordinary capacity for the formation of neomembranes. For example, there is a common intracranial tumour (meningioma), to whose source of origin reference will subsequently be made, the removal of which often necessitates not only the leaving of a defect in bone but in dura as well, so that the scalp alone covers the raw and œdematous cortical area stripped of its pia-arachnoid. The natural consequences of this would be an adherent scar between scalp and brain, with practically no re-formation of membranes, or at best of very imperfect ones, for some fluid will naturally be exuded through the intact perivascular spaces which would encourage their formation. However, should a piece of gutta percha tissue ("protective") be placed over the raw area at the close of the operation, glistening serosal surfaces will form in the manner described in a surprisingly short time, a matter of days, perhaps of hours.

Before entering into a consideration of the particular cells which take part in these reactions there is something more to be said about the processes of meningeal healing in general. Much light has been thrown on the subject by the ingenious experiments of my former assistant, Dr. S. C. Harvey, and his co-workers, who have shown the futility of patching a dural defect by the transplantation of fat or fascia as is often advocated; for if the arachnoidea over the cortex remains intact, the dura will spontaneously re-form without adhesions, whereas should the pia-arachnoid and cortex have been damaged dense adhesions will form and incorporate the dura even though its inner surface has been uninjured. In other words, as Dr. Harvey puts it, "the inner surface of the dura does not act as a limiting membrane in the presence of an attempted repair in the underlying meninges, but, on the contrary, enters intimately into the process"; and he contends that there are not only morphological but actually functional differences in the two membranes, one of which merely lines a potential subdural space, whereas the other is a more highly differentiated structure.

My own explanation of the difference in the behaviour of the two surfaces to injury would have been that the arachnoid exudes fluid, thereby providing a space which, as we have seen, becomes promptly lined by cells that migrate from the mesenchyme to make a new membrane; the dura, on the other hand, does not exude fluid, and since there is nothing to keep the surfaces apart when the pia-arachnoid has been damaged, adhesions form. But Dr. Harvey has recently brought forward additional proofs in support of his view.

He conceived the idea that the cells of the leptomeninges might be derived from the same source as the sheath cells of the peripheral nerves, which arise, as R. G. Harrison had shown, from the embryonic neural crest, whereas the dura itself merely develops from the mesenchyme. Employing Harrison's methods he removed a bit of the cerebral hemisphere of one amblystoma embryo and transplanted it into the mesenchyme in the region of the fore-limb of another, where the explant during its subsequent growth came to be surrounded by an incompletely formed dura, but with no leptomeninx. On the other hand, when a portion of the neural crest was included in the explant, a choroid plexus developed and leptomeningeal spaces were formed in addition to the duraloid membrane of the control experiment. But here again we may have to consider the normal reactions of mesodermal tissues to the infiltration into them of cerebro-spinal fluid with the inevitable formation around the fluid spaces of a serosal membrane.

This brilliant contribution by Dr. Harvey to experimental embryology and to that much neglected part of it to which Weed had already contributed—namely, the embryology of the meninges—is extremely interesting and important from many points of view; but as a matter of fact we may be stretching matters in the endeavour to show differences between the endothelium of the vascular and lymphatic channels and of the mesothelium of the serous cavities and cerebro-spinal fluid spaces; for they all are but part and parcel of the circulatory apparatus as a whole. But even though the cerebro-spinal fluid channels appear to be lined by supposedly fixed pavement cells, certain specialised cells are found to lie here and there in clusters, notably in association with the villi, in nests incorporated within the fibrous mesh of the dura, and in the leptomeningeal stalk of the plexus. It would seem to me that Dr. Harvey's disclosure of the difference in origin of these cells from those lining the dura—the one being ectodermal in origin, the other mesodermal—is of particular significance. Let us for a moment consider some of the duties of these particular cells, which, merely because of their situation and in complete disregard of their histogenesis, we may for convenience call *meningocytes*.

Phagocytic Properties of the Meningocyte.—If the pathway for this specially elaborated fluid is as important as we are led to assume, there would certainly have been provided some method whereby its intricate channels could be kept clear of debris, especially of blood or inflammatory products of one kind or another which might get into the stream, for otherwise these foreign particles would inevitably be swept into the microscopic villi and effectually stopper them. The experimental observations in this direction have been mentioned in discussing hydrocephalus. Moreover, it is safe to say that the head of every infant is sufficiently traumatised during parturition to cause the extravasation into the fluid of red blood corpuscles, so that from the first moment of extra-uterine life the mechanism for absorption for the fluid may be seriously interfered with.

An effective method of keeping these microscopic pathways open seems to have been provided through the phagocytic activity of the meningocytes under the stimulation of foreign particles. This property was first noted, it seems, by Quincke, who found that cinnabar granules introduced in the fluid become engulfed by large phagocytic cells—the same cells that Goldmann subsequently found to be stained by vital dyes; but more recently it has been shown by Essick in Weed's laboratory that, though this reaction might be evoked by a great variety of substances, it was particularly pronounced after the subarachnoid injection of laked blood, under the stimulus of which the cells enlarge, become vacuolated, and detach themselves from their moorings to swim out as free macrophages into the cerebro-spinal current. Thus Nature saw to this need from the first, and the surgeon has only just tardily come to a realisation that she can be considerably aided in her purpose by the prompt and repeated withdrawal of bloody cerebro-spinal fluid. . . .

The *plasma cells* of Waldeyer, the *mastzellen* of Ehrlich, the *endothelial leucocytes* of Mallory, the *pyrrol-zellen* of Goldmann, the *amœboid macrophages* of Metchnikoff and Evans, the *polyblasts* of Maximow, the *histiocytes* of Aschoff, and the *clasmatocytes* of Ranvier (the term in most common use by American authors) are probably one and the same type of cell which possesses active migratory and phagocytic properties. But in regard to their source of origin, their relation to the phagocytic monocytes, and their capacity for transformation into more fixed cellular types when they have ceased their wanderings, there are divergences of opinion.

Maximow, for example, claims that the three cell types in inflammation have a single origin in the lymphocyte; Sabin and her co-workers, on the contrary, strongly favour the absolute specificity of the several cell strains; the Lewises are convinced that the macrophages (clasmatocytes) and the epithelioid cells are merely functional stages of the monocytes, but make their position somewhat less clear in regard to the origin of the fibroblasts; whereas Carrel states he has definitely seen amœboid macrophages become transformed into fibroblasts. The final decision in these matters unquestionably lies with the experimental cytologists who have already devised and will further perfect methods of studying living cells in tissue cultures which permit direct observation, not only of their behaviour and manner of division, but also of their specific reactions to vital dyes.

What to the surgeon is of greater concern than the genesis of the active meningocyte is what it may be able to accomplish not only as a scavenger but also as a reparative agent. Certainly when it comes to the prompt replacement of a dural defect, say of 30 square cm., by a neomembrane, it is inconceivable that the pavement cells could grow in from the edges; and since it is doubtful whether these fixed pavement cells are capable of further division, we must assume either that clasmatocytes or monocytes have wandered in from the mesoderm or else that, in the guise of meningocytes, they are already present in the cerebro-spinal spaces and ready to act as reparative agents. In either case we must assume further that they are capable of ultimate transformation not only into pavement cells but also into duraloid fibroblasts.

Whether the cells which participate in these activities are cells which wander in or cells which in a resting stage are normally moored in the leptomeninges perhaps makes very little practical difference, provided one appreciates their behaviour when called into action.

Formation of Biliary Pigments.—There remains a further matter for consideration in connexion with these meningocytes. After Edwin E. Goldmann's discovery that the clusters of endothelial cells of the Kupffer cell type which lie clustered in the blood channels of various organs have a selective affinity for the vital stains of the benzidine series, the suggestion, I believe, was first clearly formulated by H. M. Evans that these cells as a group, wherever they occurred, within the blood-stream or free in the tissues, should be looked upon as an endothelial organ of major physiological importance which in his belief is concerned in the production of immune bodies. It is this organ to which Aschoff has recently drawn renewed attention as the reticulo-endothelial apparatus, one of the functions of which—and there are probably many—is the phagocytosis and disposal of broken-down blood-cells.

Little or no attention, however, seems to have been paid by those interested in this subject to the existence of a similar apparatus in the meninges, though Goldmann, whose early death was a great loss to experimental pathology, in the last of his remarkable papers clearly described the pyrrol-staining monocytes which normally reside therein. Though misled, as so many others have been, into the belief that the cerebro-spinal fluid chiefly escaped by way of the pericranial lymphatics, he observed that, whereas the central nervous system itself remains unstained by vital dyes, the choroid plexus as well as the anterior lobe of the hypophysis becomes highly coloured; and at the same time certain cells of the meninges (in places which we now recognise to be those where clusters of meningocytes particularly abound) and also occasional cells of the same type scattered through the brain take the stain faintly. He regarded it as probable that these cells played the essential rôle of phagocytosis for the locality.

Let us for a moment return to a consideration of the curious fact that this specialised endothelial apparatus of the leptomeningeal spaces appears to be called into action more effectively by the introduction of blood corpuscles than by any other foreign substance. And in this connexion attention may be drawn to the different behaviour of the pachymeningeal and leptomeningeal surfaces following the extravasation of blood into the subdural space, for as is well known the clot adheres to and begins to organise from the dural side, whereas it fails to adhere to the arachnoid. Now the subdural space, as we have seen, has an outer and inner lining of quite different origin, and the different manner of reaction of the two surfaces to these subdural hæmatomas has been investigated anew by my recent assistant, Dr. Tracy Putnam. He has shown how, in the process of their digestion and organisation from the dural side, communicating or non-communicating endothelial-lined spaces appear to be formed, which are distinct from the newly formed blood channels. But there is another feature of these subdural hæmatomas which seems to have escaped attention—namely, the greenish surface colour which they acquire due to the deposition of biliverdin.

The presence of bile pigments, indeed, may be identified in cerebro-spinal fluids after almost any extravasation of blood into the spaces. This is the more peculiar when one takes into consideration the fact that the bile pigments themselves do not normally pass the barrier of the choroid plexus, but are only found in the fluid in small traces in long-standing cases of deep jaundice, and perhaps only then because of functional damage to the choroidal epithelium. And though the information is not likely to be forthcoming, at least from clinical cases of icterus, I believe that even when a trace of bilirubin can be detected in the subarachnoidal fluid it will not be found in the ventricles ; and if this should prove to be so, it would indicate that the pigment finds its way into the arachnoidea by way of the perivascular spaces rather than by passage through the filter of the plexus . . . .

The Meningiomas.—There remains one thing more to say of these meningocytes. It indirectly concerns the much-mooted question as to whether the cells of the reticulo-endothelial apparatus can, as Marchand and Maximow and Carrel believe, become transformed into fibroblasts. Though this is a matter more likely to receive a definite answer by the modern methods of tissue culture and supravital staining which would permit the transformation to be actually observed, nevertheless clinical and histopathological experiences may add something to the subject. And this leads me to speak of the tumours which might be expected to take origin from the cells of the apparatus under consideration, if it actually possesses the important physiological functions ascribed to it.

Endotheliomata, so-called, are known to arise in the liver, spleen, bone-marrow, and lymph glands where the cells of the apparatus in question abound, but in no situation are tumours of this category more common than in the meninges. They, consequently, are lesions long familiar to the pathologist and to the neurologist. A famous example, often referred to, was reported (as a sarcoma) by Byrom Bramwell in his early monograph on " Intracranial Tumours " (1888)—a young girl of 20 who had been admitted to the Newcastle Infirmary, Jan. 5th, 1877, in a terminal stage of compression from a growth which had given no localising symptoms. This, be it said, is a characteristic of these meningeal tumours, to slowly deform the brain in which they make a nest for themselves, often without any local symptoms whatsoever, nor indeed any pressure symptoms until the lesion may have attained an amazing bulk.

These tumours all have a common histogenesis, whether they occur in the spinal canal, taking their origin from the cells of the arachnoidal villi at the points of emergence of the spinal nerves, or as is more frequent from those which project into the venous sinuses of the cerebral dura. Unfortunately, however, they have been given by histopathologists so great a number of conflicting names that it has seemed best, partly for the purpose of emphasising their common origin and partly to get away from the unfortunate misnomer of " dural " endothelioma, to speak of them simply as meningiomas.

To the fact that they undoubtedly arise from the arachnoid cell-clusters of meningocytes Dr. Weed and I called attention in one of our early papers, though, as we found, it was not an original observation, for the suggestion had been made before by M. B. Schmidt (1902), and also long before him (1864) by the late Prof. Cleland, of Glasgow. But no one seems to have offered any explanation of the remarkable fact that the tumours invariably take their origin from the arachnoid and never from the pial side of the fluid pathway, for though " endothelial " tumours may in rare instances appear to arise from the pia they are of vascular and not mesothelial origin . . . .

Though we have only made a small beginning in the study of tumour cells by modern culture methods, such as have permitted Alexis Carrel to see macrophages become transformed into sarcoma cells, we have at least succeeded in cultivating the cells of a meningioma, and have seen cells which, unstained, were indistinguishable from tumour cells, engulf red blood corpuscles. Only by the employment of such methods can light be thrown on the much-mooted question as to whether the meningocytes actually become transformed into fibroblasts. The larger number of these clinically unmistakable tumours are almost wholly composed of endothelial cells, but certain of the older and psammomatous growths come to take on a fibrous change and may actually contain deposits of true bone ; but even in the more purely fibrous examples one may always find nests of mesothelial cells. From this histological evidence, if it is dependable, one would certainly be led to conclude that the cells comprising the reticulo-endothelial apparatus of the body, and of which the cell clusters of meningocytes are obviously important representatives, may actually undergo fibroblastic transformation.

Thus we have seen whence the cerebro-spinal fluid takes its origin, how it comes to make pathways for itself by percolating through the primitive mesenchyme, how these pathways which originate from cells of the neural crest become lined with a specialised mesothelial membrane, and how minute outlets for the absorption of the fluid into the large venous channels are formed—in short, how this circulatory switch for a fluid peculiar to the ventricular and meningeal spaces comes into existence, and how it communicates with the deeper parts of the brain by perivascular tubes of the pia-arachnoid.

We have seen, too, that in addition to the fixed pavement cells lining these spaces certain other cells termed meningocytes tend to become deposited in clusters which we may figuratively describe as moored fleets of destroyers ready to cast off and engage any objectionable invader. In this respect the phagocytic functions of these cells are in every way comparable to those exercised, for example, by the clusters of Kupffer cells in the hepatic vessels, for they have the same affinity for vital dyes, the same capacity to engulf and destroy red blood corpuscles, elements which are foreign to the circulating medium of the meningeal spaces, and they possess also the capacity in this process of blood destruction of transforming hæmoglobin into bilirubin. Hence these cells may be taken to represent the reticulo-endothelial apparatus for the meningeal spaces.

We have seen also how these clusters of meningocytes may become the seat of tumefactions which, because of their being in most cases incorporated with the dura, are commonly supposed to arise from it, but which actually take their origin from the meningocytes and may be conveniently designated as meningiomas. And it would appear from the study of these tumours that their endothelial ground cells may become metamorphosed into fibroblasts.

So by a consideration of the cerebro-spinal fluid and of the cells of the membranes which enclose it, one may be led into problems of wide concern in general pathology. But with the indented purpose of this lectureship in mind, it is improper to leave the subject without calling attention to the fact that, though we may not appear to be much nearer to a cure for congenital hydrocephalus in quest of which we started out, we have at least learned many things on the way which are essentially of practical therapeutic value.

ANATOMICALLY IRREGULAR SPHENOIDAL SINUSITIS WITH OPTIC NEURITIS,

LOCALISED BY THE SUCTION SYRINGE; WITH TWO EXAMPLES.

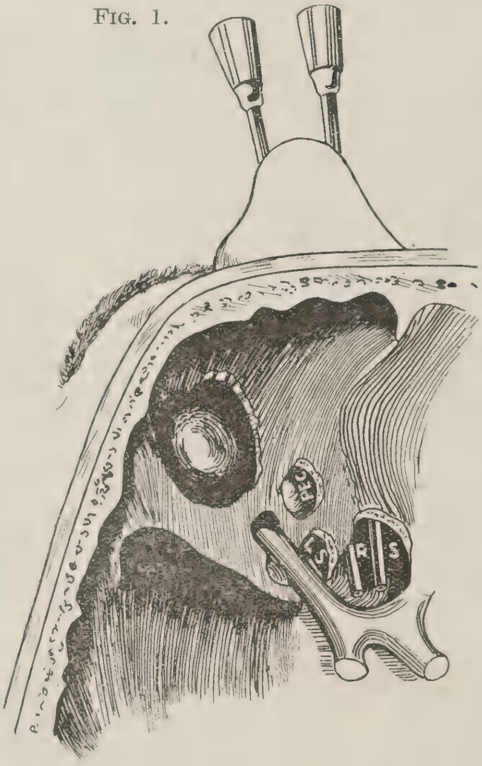
BY PATRICK WATSON-WILLIAMS, M.D. LOND.,
CONSULTING SURGEON FOR DISEASES OF EAR, NOSE, AND THROAT, BRISTOL ROYAL INFIRMARY.

THE occurrence of so-called "canalicular optic neuritis," enlargement of the blind spot, and relative scotoma, due to pyogenic infection in the sphenoidal sinuses or posterior ethmoidal cells, or less frequently in the other nasal sinuses, is well recognised, and the detection of the infective focus by the suction syringe has been described in previous communications by the writer.[1] The investigation of the sinuses in patients suffering from these optic nerve defects suspected to be of nasal origin, sometimes present special difficulties, owing, on the one hand, to the absence of any visible purulent discharge,[2] and on the other to the irregular anatomical conformation of the sphenoidal sinuses and the ethmoid cells.

Anatomical Variations in Sinuses.

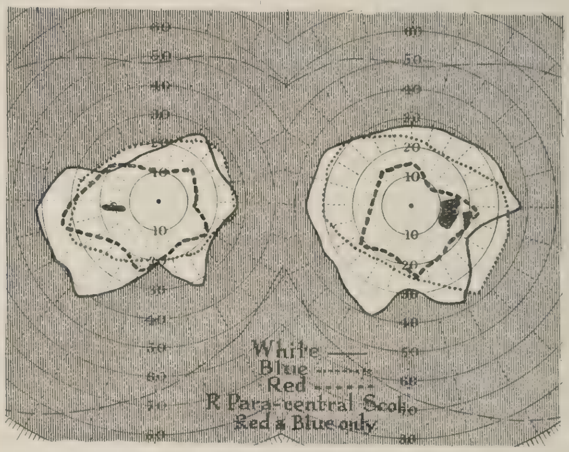
Thus, one sphenoidal sinus may be large and over-developed at the expense of the other, so that the large sinus extends far beyond the mid-line and consequently the small ill-developed sinus may be, so to speak, packed away into a corner difficult of access. Again, the posterior ethmoidal cell may be unusually large and over-developed at the expense of the corresponding sphenoidal sinus, which may be so encroached on that the large ethmoidal cell occupies more or less the usual site of a sphenoidal sinus or it may lie above the sphenoidal sinus, much as a first floor room lies above the corresponding one on the ground floor. While these anatomical variations are of no moment in health, it is quite another matter when the sinuses become infected and the focal infection causes partial or complete loss of vision, or, may be, is the primary and essential cause of rheumatoid arthritis, neuritis, neurasthenia, unsoundness of mind, and so forth, any or all of which do occur. If there is plentiful purulent discharge the indications for opening and draining the involved sinuses are sufficiently plain, but unfortunately such cases are less frequently associated with the complications mentioned than are the cases where the discharge is slight, macroscopically non-purulent, and often unnoticed until inquired into. It is therefore important to detect and to localise precisely the source of any infective focus and, when confronted with anatomical irregularities in these, relatively small deep-seated sinuses, to avoid overlooking the focus, an error which may cost the patient his sight or worse.

FIG. 1.



CASE 1.—Showing the cannulæ passed through the right and left nasal passages, but both entering the large right sphenoidal sinus (R S). It will be seen that both optic nerves are in anatomical relationship with this one sinus, hence both eyes affected. The small left sinus (L S), which was proved non-infected, is lying well to the outer side of the median line.

L. FIG. 2. R.



CASE 1.—July 4th, 1922. (McH. perimeter and scotoma verified by Bjerrum screen.) The visual colour-fields are all markedly contracted. The right eye chart also shows the large relative central scotoma and a smaller paracentral scotoma for red and blue only.

Clinical Records.

The two subjoined examples afford an interesting contrast; in the first the large sphenoidal sinus was infected and the smaller was sterile; in the second the large sinus was sterile and the small one, so difficult to locate, was highly infected. In the first case I failed to detect my mistake until I was led to make a further exploration; this helped me to avoid a similar mistake in the second, where the error would have been disastrous to the patient, because I should perhaps have left the essential focus unrelieved.

I know of no means, other than that of the adaptation of the method of exploration by the sinus syringe, by which the focal infections could have been localised during life; while post mortem such localisation could only have been of academic interest.

CASE 1.—C. R. D., male, aged 21, was referred to me by Dr S. H. Modi (Calcutta) and Dr. F. Gotla (London) for chronic sinus infection with headaches, mainly right supra-orbital. At age 9 he had undergone operation for removal of tonsils and adenoids, at age 13 further operation of turbinectomy, and again turbinectomy at age 15. At age 19 the right antrum was opened and drained, that was two years before I saw him. (Fig. 1.)

When I explored his nasal sinuses the right antrum yielded thick ropes of pus by the suction syringe, the left being clear.

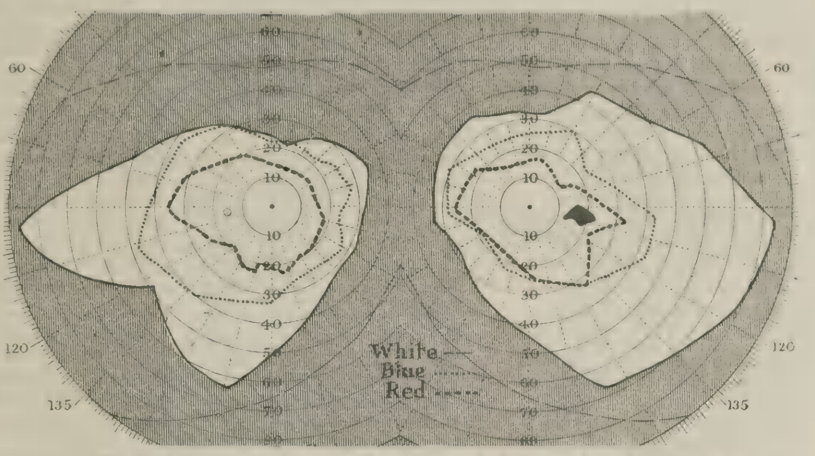
[2] Les Sinusitis sans Pus. P. Watson-Williams, Archiv Internat. f. Laryng., &c., April, 1922.

The sphenoidal sinuses were explored and "found to communicate"; and further, the posterior ethmoidal cells were explored by cannula and suction syringe.

Film stain and culture of the sinus contents by Dr. A. T. Todd yielded results as follows: Both maxillary antra and the large right sphenoidal sinus and the posterior ethmoidal cells right and left yielded pneumococcus, polymorphonuclear cells being present in every one. But the small left sphenoidal sinus that was detected and explored later yielded neither organisms nor polymorph leucocytes, thus showing that it had escaped infection.

FIG. 3.



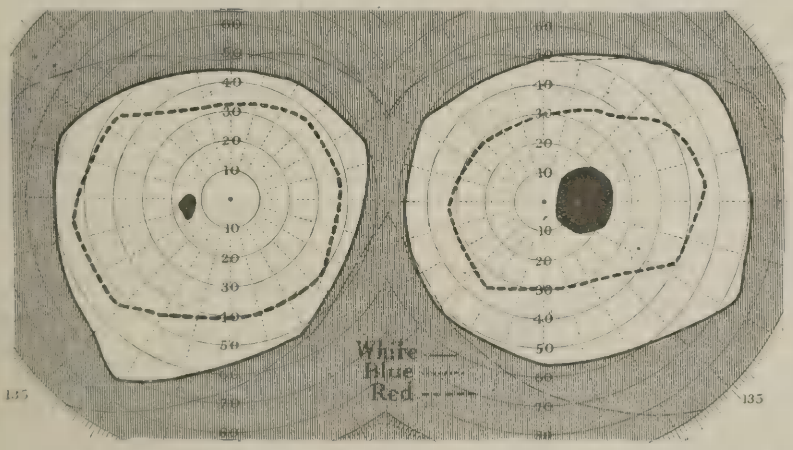
CASE 1.—Nov. 10th, 1922. Scotoma in R smaller and the paracentral scotoma gone. (Later, September, 1923, white fields normal.)

Examination of Visual Colour-fields, &c.—Ocular details of Mr. A. E. Iles's reports are given below under the various dates. It suffices here to state that his first revealed right enlarged blind spot and paracentral scotoma for red and blue; the left eye being normal and so corresponding to the non-infected sphenoidal sinus. (Fig. 2.)

It had appeared from the first nasal exploration that the right and left sphenoidal sinuses were both infected, but this was an error due to the one large sinus having been entered through both nasal passages. Further examination was therefore made and, by directing the cannula more outwards, one entered the true left sphenoidal sinus well to the outer side of what had been mistaken for the left sinus, and this latter did not communicate with the more central sphenoidal sinus on this the left side. Cultures of the sphenoidal sinuses showed that the smaller left side sinus which was outside the mid-line was non-infected, while the more central sinus, entered through the left nasal passage which was really the right extending across and encroaching on the left side, was highly infected with streptococcus, &c. Hence the explanation of canalicular optic neuritis restricted to the right side with apparently a double sphenoidal sinus infection.

All the nasal sinuses were opened and drained pernasally, and later a submucous resection of the septum was done to afford a more normal nasal air-way. As the result of the pernasal operations the visual colour-fields, as well as the general condition of the patient, became greatly improved. (Fig. 3.)

FIG. 4.



CASE 2.—Visual colour-fields and blind spots. (McHardy perimeter and enlarged blind spots verified by Bjerrum screen with 1 mm. white disc.) (Mr. E. R. Chambers.)

Reports by Mr. Iles.—Vision in each eye 6/5.

4/7/22: Fields show enlarged blind spot for red, white, and blue on right side; contraction of blue field, especially nasally right and to a less extent left. Small paracentral scotoma *red and blue* right eye.

10/11/22: Scotoma smaller, field fuller, especially R.E. white.

12/5/23: States that the right eye has "become smaller"; this was not found to be the case; the eye was as prominent as the left; no squint was detected by any test.

8/9/23: Still discharge from the nose. Paracentral scotoma right eye *to blue only*. White field not yet full, but fields of vision, especially as regards the blind spot, show improvement.

CASE 2.—C. E. C., male, aged 41, July, 1924. Markedly defective vision in right eye, which had persisted since influenza 14 months before, attended with severe pain at back of eyes and photophobia, and followed by double vision on looking towards right. Diplopia increasing, he consulted Mr. H. Snell, who noted paresis of right external rectus and suspected dental sepsis which, however, was excluded. Visual defects increased in right eye, objects being seen dimly, and Mr. Snell found the right eye divergent, the right optic disc slightly pale on the temporal side, and a central scotoma, but visual fields normal. The left eye he reported normal. The patient had noticed no nasal catarrh, but the rhinologist to whom he was referred kindly sent the following note:—

"No pus seen in nose. Sphenoid and posterior ethmoid cells washed out with Watson-Williams' syringe, also right antrum—washings clear. Culture report: No growth obtained on aerobic cultivation for 48 hours."

The negative nasal findings in view of the symptoms at this stage led to the case being diagnosed as a missed encephalitis lethargica.

Meanwhile the post-nasal catarrh had become much more noticeable, and it was at this stage, 14 months after the initial attack, that the patient came under my notice.

The fundus oculi and visual colour-fields, right and left, were examined by Mr. R. E. Chambers, who found a very large blind spot on the right side and some contraction of visual fields, both fundi normal, and no trace of diplopia nor of past optic neuritis. Anterior rhinoscopy revealed nothing abnormal and no discharge observed. Endorhinoscopy (Holmes) showed only a few indefinite strings of muco-pus, but the mucosal vessels were abnormally full on the right side posteriorly. (Fig. 4.)

Exploration by the Author's Suction Syringe.—Right antrum.—Film stain: A little pus, mononuclear polymorphs, some phagocytosis, streptococcus. Culture: Pure streptococcus. Left antrum.—Film: Occasional leucocyte. Culture: Negative. Right sphenoid.—Film: Mononuclear pus, streptococcus, no phagocytosis. Culture: Pure streptococcus. Left sphenoid (per right nose): Debris only. Culture and film negative. Right posterior ethmoid.—Film: Mucus—few mononuclears. Culture: *Staphylococcus aureus* only. (Fig. 5.)

After repeated lavage, &c., of the opened sinuses, Mr.

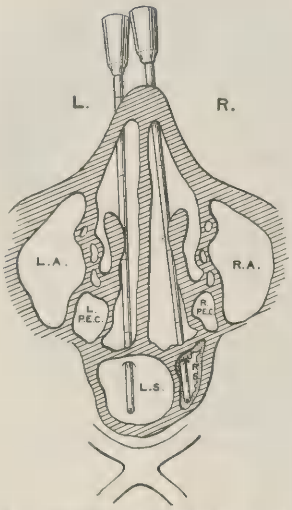
Chambers examined the eyes and reported August 16th, 1924 —i.e. five weeks after his first report: Vision in both eyes normal, visual fields for white and colours quite full, and there was no pathological blind spot selected by the perimeter. Central colour vision normal.

Seen again and tested in October, 1924, and he was then normal in every way from the ophthalmological point of view.

Discussion.

An interesting point is that the sterile left sphenoid extending well across the midline was entered as readily through the right as through the left nasal passage. Suspecting, therefore, that the right sphenoid was probably small and ill-developed and had been missed, another cannula was entered, directed well outwards, and the real right sphenoid was thus entered and explored, and yielded pure streptococcus on culture and film. The test applied was as follows. Two cannulæ were inserted, one through the right nasal passage, the other through the left, so that both had entered what was presumed to be the large left sphenoidal sinus. Then, on attaching a syringe to one cannula and syringing down sterile water, it escaped out through the cannula in the other side. Again two cannulæ were inserted both through the right nasal passage, one into the left sphenoid, the other directed outwards to enter the right sphenoid sinus, and on syringing water down the one it did not come up and escape by the other, showing that the two cannulæ passed in through the right nose were in different cavities. This is the method I usually adopt to determine whether one has entered one cavity with two cannulæ or that the two cannulæ are in different, though adjacent, cavities and was used in connexion with both of these cases.

FIG. 5.



CASE 2.—The cannula in order to enter the small infected right sphenoidal sinus had to be directed well to the outer side.

The practical point is that one thereby gains precise information as to the actual source of the extracted sinus contents and the bacteriological investigation tells us whether it is or is not infected.

CONGRESS ON VENEREAL DISEASE AT PARIS.—Following the Wembley Congress, organised by the British Social Hygiene Council, a meeting was held in Paris of the Union Internationale contre le Peril Vénérien, where decisions were taken with a view of further combating venereal disease. Great Britain, France, Germany, the United States of America, and 12 other countries were represented by delegates from the recognised social hygiene organisations, by delegates from the various National Red Cross Societies, and by a number of official Government representatives. Of the many decisions reached the most striking was the unanimous decision that the regulation of prostitution was inconsistent with efforts to eliminate venereal disease. This same point was brought out so long ago as 1913 at the International Medical Congress held in London. In Paris the system of control of prostitution was condemned on medical grounds, and thus after 12 years the decision reached in London was endorsed. The Congress dealt particularly with the difficulty of eliminating disease from the mercantile marine, with the measures which should be taken in connexion with frontiers, with the problem of prostitution, and with emigration situations. Certain of the shipping interests agreed cordially to coöperate by financial assistance with the measures recommended in the mercantile marine. The Council of Direction adopted a report recommending measures against prostitution. These include wider propaganda and stricter legislation.

THE RELATION OF NEPHRITIS IN EGYPT TO INTESTINAL INFECTION.

BY H. B. DAY, *M.C.*, M.D., F.R.C.P. LOND.,
LATE PROFESSOR OF CLINICAL MEDICINE, ROYAL SCHOOL OF MEDICINE, CAIRO.

IN a paper published in THE LANCET[1] five years ago I stated that nephritis, as met with in Egypt, was usually due to bacilli of coliform type derived from the intestine. This opinion was based on the results of bacteriological examination of the urine, the experimental reproduction of nephritis in animals by injection of the bacilli isolated, and the favourable effect of vaccines in human cases. These findings are not supported by the general run of experience in this country. Most observers report that streptococci appear the commonest cause of acute glomerulonephritis and that in many patients sore throat precedes the attack.[2, 3] In some cases, however, coliform bacilli are deemed responsible, especially when signs of urinary tract infection are present.

In this paper I wish to bring forward evidence to show that in Egypt we have largely to deal with a form of nephritis that is intimately connected with intestinal disease. For this purpose I have analysed some 100 cases of nephritis with œdema admitted to my wards in Kasr-el-Ainy Hospital, Cairo, during the last few years. The distinguishing feature of œdema has been chosen as indicating a lesion sufficiently advanced to cause failure of an important renal function and not as a necessary criterion of acute or parenchymatous nephritis. While the ordinary case of granular kidney has thus been excluded, a further omission has been made of renal patients who had developed dropsy in connexion with signs of heart failure.

Clinical Types.

For investigations into ætiology, the more acute forms are most suitable. Hence a simple division of the series into (*a*) acute, (*b*) syphilitic, and (*c*) chronic forms has been made. The distinction between acute and chronic cases is beset with certain difficulties, but apart from considerations of onset, duration, symptoms, and course, there is one feature which certainly reveals the existence of an acute inflammation of the kidneys—namely, the presence of abundant blood casts or cellular casts in the urine. This feature has therefore been taken as the main criterion of an acute nephritis, although perhaps unduly exclusive. To this group one-third (34 cases) of the total number belong. In five patients out of the total of 100 there was strong evidence that syphilis was responsible for the renal lesion. These cases have been grouped together irrespective of the nature of onset or the duration of their symptoms. The remaining group, comprising 61 out of 100 cases, is mainly composed of chronic forms of nephritis. In what proportion the onset had been acute or gradual was impossible to determine; five patients described a previous attack with subsequent return of dropsy.

Causative Factors.

Antecedent Conditions.—In 85 per cent. of the acute cases there appeared a causal connexion between the renal inflammation and some antecedent or concomitant infection. A similar connexion could only be established in a minority of the more chronic forms, for the patients had often forgotten slight illnesses in the past, and the appearance of œdema only fixed the date of gross renal failure and not necessarily the time of onset of kidney disease. Among 27 cases of acute nephritis whose clinical history was recorded, no less than 20 had been incapacitated by a definite illness for some time prior to the appearance of renal symptoms. This history was often substantiated by the persistence of such antecedent symptoms after admission to hospital, while other patients showed similar signs which had not been the subject of complaint owing to their milder nature.

These preceding conditions are tabulated below :—

—	Antecedent history of	Persisted on entry.	Found in others.
Fever—generally prolonged	8	6	6
Fever followed by dysentery or diarrhœa ..	7	4	2
Acute dysentery	5	1	2
Total	20 (of 27)	21 (of 34)	

In no instance could an antecedent fever be identified with scarlet fever; the prolonged course was usually sufficient to negative this. The fever was proved to be malaria in one patient, and in two others may have been due to an acute pyelitis.

While the importance of bowel infections is brought out in the above table, examination of the patients disclosed some conditions frequently associated with nephritis, which explained the significance of the fever and dysentery described.

(*a*) *Bilharzia Mansoni Infection.*—Definite signs of this were present in 55 per cent. of acute cases of nephritis, a much higher proportion than is found among hospital patients in general. The early signs are prolonged fever followed by more or less dysentery (often transient), and later an enlargement of the liver and spleen. Egyptian patients only notice these symptoms when pronounced, and frequently one or other is slight. Hence it appears that the preceding illness described by so many patients was due to this type of bilharzial infection, and that nephritis was apt to occur at the time when ova had made breaches in the intestinal mucosa. Among patients admitted for splenomegaly in a later stage without obvious intestinal lesions, there was no special tendency to nephritis. But renal disease was fairly common in cases of chronic bilharzial dysentery or advanced cirrhosis, when the general wasting and loss of resistance associated with hepatic and pancreatic insufficiency often predisposed to intestinal disorder and infection.

(*b*) *Bilharzia Hæmatobium Infection.* — Urinary bilharziasis was found in one-third of the renal cases, an incidence too low to be significant in itself, considering the wide prevalence of this disease. But while bilharzial disease of the bladder alone appeared to have little influence on the development of nephritis, the frequent involvement of the ureters undoubtedly predisposes to renal infection. The experiments of Lepper[4] showed that injections of *B. coli* into the blood-stream of rabbits regularly caused kidney lesions if the ureter was temporarily obstructed.

(*c*) *Intestinal Worms.*—Of these infestations, so common in Egypt, ankylostomiasis was most frequently associated with nephritis, though much less often than affections of the large intestine. Mistakes in diagnosis may occur in severe cases of anæmia when widespread œdema is present and sometimes albuminuria from œdema of the kidneys, thus simulating nephritis.

Bacteriological Results.

A routine bacteriological examination of the catheter urine was made in every case, and the results confirmed the work mentioned previously. Great care is necessary in the collection of samples and was rewarded by very uniform results in males, though in females contamination was relatively frequent. The procedure adopted was as follows :—

The external parts were carefully cleansed with antiseptic solution; since male Egyptians are circumcised one source of contamination was absent. A soft rubber catheter was passed by gloved hands and some urine allowed to escape. An attendant then compressed the catheter; the end was flicked clear of urine and sterilised in a flame. A few c.cm. of urine were next collected quickly in a sterile tube during momentary removal of its rubber stopper. The specimen was kept standing for an hour (unless turbid) to allow suspended matter to settle, when a culture tube was inoculated from the deepest portion. The culture and urine tube were kept 24 hours at 37° C. Should the culture tube show no growth in this time a fresh inoculation was made from the deposit in the urine tube that had been incubated for 24 hours.

The results may be summarised thus :—

(*a*) In cases of acute nephritis positive results from the first culture were almost invariably obtained. One patient—seen in private and not included in the series—gave a negative result on two separate occasions. In this case the acute nephritis had followed influenza, and ordinary media were used.

(*b*) The urine from cases of chronic nephritis showed a general correspondence between the microscopical picture of the sediment and the bacteriological examination. When cells were visible, included in the casts or free, a positive culture was usually obtained either from the fresh or the incubated specimen. If only granular and hyaline casts were present the urine proved sterile in the great majority of cases.

(*c*) The three uncomplicated cases of syphilitic nephritis showed a sterile urine.

(*d*) From patients whose urine contained definite collections of pus cells, usually from a cystitis complicating old bilharzial disease, a growth of staphylococci was usually obtained, either pure or in addition to bacilli. When there was much pus a bacillary or mixed growth was the rule. Streptococci were found in one case of septic nephritis.

(*e*) In uncomplicated cases of nephritis a pure growth of bacilli of intestinal types was generally found on culture of the urine. Their cultural properties were investigated by Dr. J. K. Clarke, who found that most belonged to the coli-typhoid type. Alkaligenes, non-lactose fermenters, and *B. pyocyaneus* were found in several.

Experimentally, the nephrotoxic properties of these organisms varied considerably. The more typical *B. coli* obtained from cases of nephritis with obvious bacilluria had little effect, whereas the coliform organisms obtained from the more common form of nephritis reproduced nephritis in a series of animals inoculated either subcutaneously or intraperitoneally. A diversity was also noted by E. Lepper, who reported that one strain of *B. coli* used in her experiments had a decided toxic action on the kidneys of rabbits injected intravenously.[4] The effect on the kidneys persisted long after the initial phase of bacillæmia in the animals, and similar lesions were found in the liver, as in cases of nephritis induced by chemical poisons. The staphylococci found in cases of pyuria had no selective effect on the kidneys of animals injected.

Agglutination tests on patients yielded unsatisfactory results, in keeping with the similar experience of pathologists regarding simple bacilluria.

Complications.

Among the complications that developed in the course of a nephritis there are two forms of special importance.

1. *Respiratory.*—Bronchitis was tolerably common and evenly distributed among the various groups, occurring in five acute, one syphilitic, and nine chronic cases, but it appeared more commonly as a later complication than an antecedent condition. In one patient pulmonary tuberculosis definitely preceded nephritis. One renal case was admitted with severe pneumonia which proved fatal, and another died as the result of an acute serositis affecting the pleuræ and peritoneum. During their stay in hospital two patients contracted influenza (then epidemic), another developed broncho-pneumonia, and three others a febrile pleurisy. In all six patients recovery was uneventful and only temporarily delayed progress.

2. *Intestinal.*—An acute febrile diarrhœa or dysentery developed suddenly in nine of the nephritis cases. Unless promptly controlled this complication had a most prejudicial effect on the renal and general condition, and in four cases was rapidly fatal. There is much reason to fear that cross-infection from other patients suffering from intestinal disease was often responsible—a disaster most difficult to avoid with patients of the most unhygienic habits in crowded wards. The condition certainly seemed of infective origin, and in most of the patients there was no apprehension nor signs of uræmia beforehand.

Treatment.

As a result of the investigations described—both clinical and bacteriological—the conclusion seemed warranted that most cases of nephritis in Egypt arose as a complication of an intestinal infection. Hence the opportunity was taken to treat suitable cases on this assumption, while not neglecting usual measures. For the ordinary case without present diarrhœa, the usual purgative treatment given for acute nephritis may help to diminish a source of intoxication. Intestinal antiseptics proved of very limited value. For patients with obvious intestinal lesions a direct therapy was indicated. Some forms of chronic dysentery of amœbic or bilharzial origin responded to emetine injections and showed a distinct improvement in the renal condition as soon as the intestinal infection was controlled. Similarly patients with nephritis complicating ankylostomiasis benefited by specific treatment, as in the case illustrated by Chart 1.

A man of 25 had suffered from fissure of the anus for six months and general dropsy for the last four months. On admission there was extensive œdema with ascites. The urine contained a large trace of albumin with fine, long granular and a few larger cellular casts. He was anæmic (Hb. 60 per cent.) and the stool contained ankylostoma ova. Appropriate anthelmintics were given in addition to the usual treatment for nephritis. A slow improvement followed, with a sudden diuresis as soon as the worms had been removed. In about three weeks after entry the dropsy had disappeared with a loss of 30 lb. in weight.

For acute cases of nephritis and pyelitis when bacilli were plentiful in the urine, the free administration of alkali appeared beneficial, as in bacilluria. Urinary antiseptics were of little avail and the impaired excretory powers of the kidneys prevents the usual degree of concentration in the urine.

Vaccine treatment proved the best means of treatment in most cases of bacillary nephritis. Some examples of their action have been given in a former publication,[1] but here I wish to describe a few cases which illustrate special points in their use. Chart 2 shows the effect of small repeated doses in a chronic case which had not responded to the usual treatment.

A man, aged 26, was admitted for general œdema which had lasted for 14 months. The urine averaged 900 c.cm. daily with a low sp. gr. but an albuminuria of 6 parts per 1000. There were irregular recurrences of fever with chronic enlargement of the liver and spleen, not at that date recognised as evidence of *Bilharzia mansoni* infection. Examination of the urine showed a deposit of muco-pus containing some granular casts, and a catheter specimen gave a good growth of a coliform bacillus. The administration of an autogenous vaccine induced a definite diuresis with relief of œdema.

Through the courtesy of a colleague, Dr. Abd'el Aziz Ismail, I was enabled to try vaccine treatment on a case of nephritis when the patient stayed sufficient time in hospital to show the full effect (Chart 3).

A male, aged 40, had suffered from severe dysentery for six weeks, and for the two months following from an œdema which had reached formidable dimensions by the time of admission. There was irregular fever associated with chronic dysentery (five to six stools daily), probably founded on bilharzial infection. The urine showed the usual features of a chronic nephritis. In this case urea was tried as a diuretic on account of the oliguria present; its use was followed by a marked rise in the amount of urine excreted, but the albuminuria just afterwards increased from 3 to 10 parts per 1000. Meanwhile emetine injections had been given perseveringly, but without effect so far on the fever and dysentery. The injection of an autogenous vaccine had a diuretic effect, and the albuminuria was reduced. Continued treatment with emetine and vaccine resulted in abolition of the fever, then abatement of the diarrhœa, with a marked diuresis and disappearance of the dropsy. The albumin diminished rapidly to a trace.

Experience in other cases showed that vaccines generally had a very definite effect on the renal condition and often on fever, if present, but did not check a diarrhœa. The explanation is probably that diarrhœa results from various lesions, such as ulcers originally due to amœbic or bilharzial infection through which coliform bacilli have been absorbed. Appropriate vaccine then checks the effects of such absorption without influencing the intestinal lesion.

While an autogenous vaccine was naturally preferred, equally good results were often obtained from an allied strain of organism. In one patient temporary improvement followed the use of a stock vaccine, while an autogenous vaccine used later brought about a relapse. In the light of later experience this anomaly is explained by the inappropriate dosage, a matter of considerable importance.

The first patients selected for vaccine treatment were non-resolving cases of nephritis in whom œdema persisted. These reacted to doses of 25 to 50 millions as a rule. But when the nephritis is acute, with oliguria or fever, or if high albuminuria is present, the kidneys seem much more sensitive and such doses may do more harm than good. Should a non-autogenous vaccine be used, a comparatively large dose may prove safe and beneficial when the same dose of autogenous vaccine is too large. A particularly interesting case, illustrating the importance of the right dose, is shown in Chart 4.

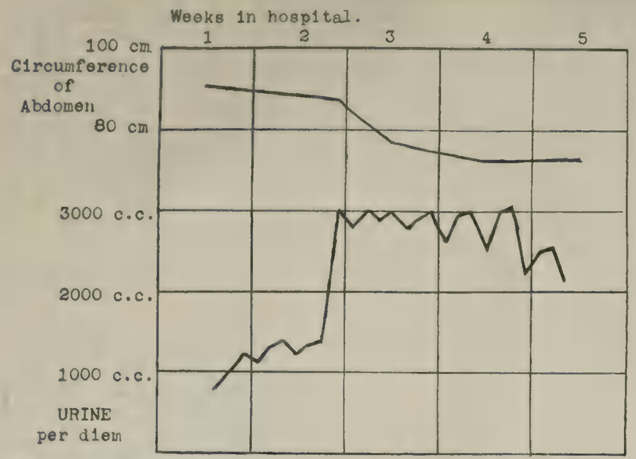
The patient, a woman of 25, who had had no previous illness nor been pregnant, was admitted to another section for a general œdema of a fortnight's duration. The daily quantity of urine averaged 600 c.cm. and there was a considerable amount of albumin. Under the usual treatment the œdema diminished and the output of urine rose to 900 c.cm. when she took her discharge. A week later the dropsy recurred and so rapidly increased that in a few days she returned to hospital and was admitted to my ward. Her condition now resisted the treatment which had proved beneficial before. The urine averaged 750 c.cm. daily, with an albuminuria varying from 10 to 20 parts per 1000, and contained a large number of casts—granular and hyaline with few included cells. There were no signs of complicating disorders, and the Wassermann reaction was negative. A catheter specimen gave a good growth of Gram-negative bacilli, which did not ferment lactose. Renal efficiency tests gave good results; the urea concentration was high, blood-urea 61 mg. per 100 c.cm., and the phthalein excretion 43·5 for the first hour and 32·5 for the second. The blood pressure was normal: 120 and 80 mm. Hg.

The condition therefore corresponded clinically to Epstein's nephrosis. Intravenous injections of calcium chloride and the administration of urea by mouth (15 g. daily) were ineffective. Increased protein feeding unfortunately increased the œdema and was abandoned.

Vaccine treatment with the bacillus found in the urine was begun with an initial dose of 25 millions which rather aggravated the oliguria, and smaller doses of 10 and 15 millions used subsequently failed to improve her condition. The patient had now been two months in hospital without benefit. I then tried giving the vaccine by mouth on an empty stomach. The first dose, 15 millions, caused a slight fall in the urinary excretion followed by a gradual rise; a week later a dose of 20 millions by mouth caused a fall without a rise later. A third dose of 15 millions caused no fall, but the later effects were apparently neutralised by the onset of a septic infection in the flank accompanied by fever. As soon as this subsided the oral administration of the vaccine was recommenced, using quite small doses, 10-15-20 millions at short intervals. This induced a diuresis which removed the extensive œdema. Owing to the breakage of the bottle the autogenous vaccine was lost, but fortunately a substitute vaccine tried proved equally efficacious.

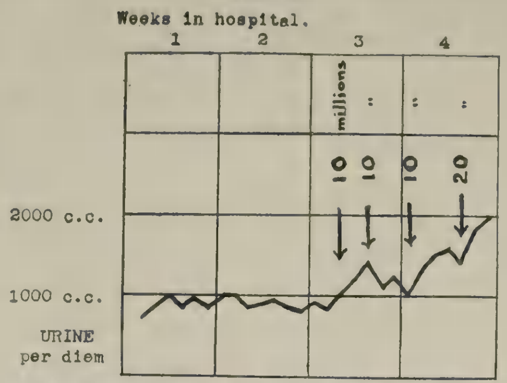
On discharge there remained an albuminuria of about 5 parts per 1000. The patient attended regularly as an out-patient and at first showed an increase of albuminuria

CHART 1.



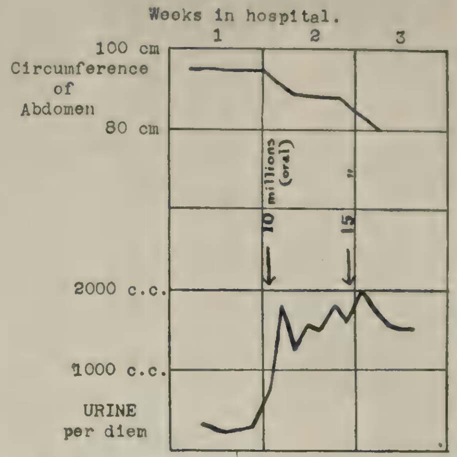
Case of ankylostomiasis complicated by nephritis with general œdema and ascites for four months. Anthelmintic treatment caused a gradual improvement with a sudden diuresis as soon as all the worms were expelled.

CHART 2.



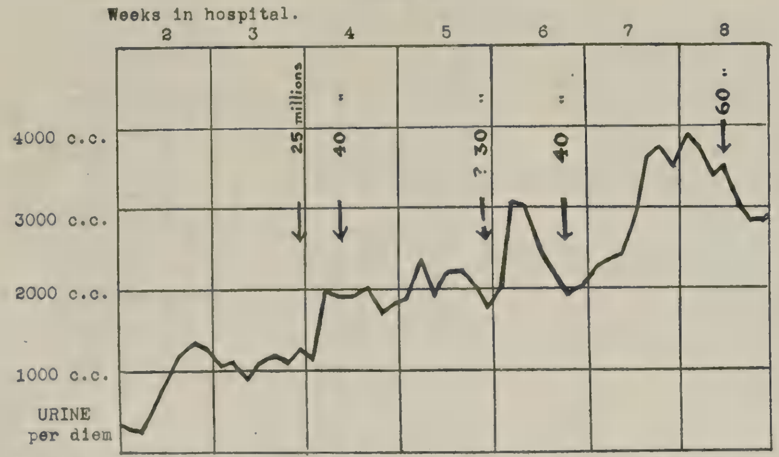
Case of chronic nephritis with œdema that had persisted for 14 months. Patient had *Bilharzia mansoni* infection with recurrences of pyrexia. Treatment by injection of an autogenous vaccine, as indicated by the arrows, caused diuresis and relieved the œdema.

CHART 5.



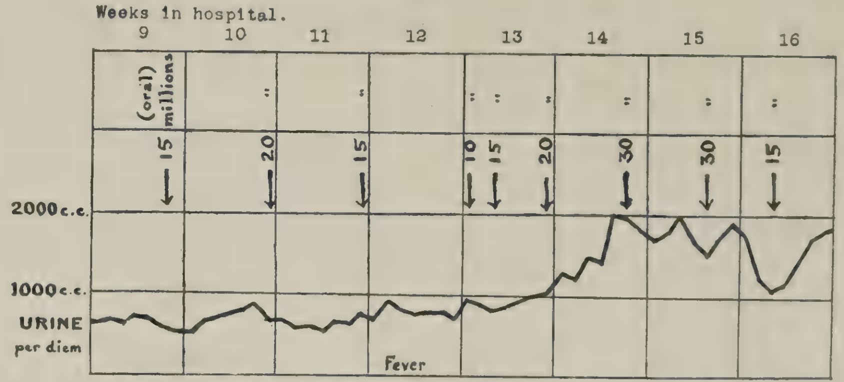
Case of severe nephritis with high albuminuria, oliguria, and extreme dropsy with ascites. Chart shows immediate diuresis (accompanied by a striking diminution in the albuminuria) on treatment by vaccine given orally. This occurred in spite of an acute diarrhœa and fever that had developed two days before.

CHART 3.



Case of prolonged dysentery with fever (due to *Bilharzia mansoni* infection) complicated with nephritis. On admission there was much œdema and oliguria. The chart shows some diuresis in the second week following the administration of urea. An autogenous vaccine was afterwards given by injection as indicated in the chart. Emetine was given during the third, fourth, and fifth weeks. The fever and dysentery declined in the sixth week. By the eighth week the albumin had decreased to a trace; the diuresis continued for another month.

CHART 4.



Case of prolonged nephritis with much œdema and high albuminuria. No improvement took place during the first eight weeks in hospital, before the chart commences. The chart records the effect on the urinary output of doses of an autogenous vaccine given by mouth. The last dose shown was of a substitute vaccine.

with a slight return of œdema on the resumption of her ordinary life, but with weekly doses of vaccine (oral) the albuminuria was reduced till it reached a steady level of 3 per 1000.

Since no further improvement was expected, the patient was again admitted to hospital. The phthalein test now revealed a considerable deterioration of renal efficiency, the figures being 11 per cent. in the first hour and 14 per cent. in the second, a total of 25 as compared with 76 obtained six months previously. Decapsulation was therefore performed on both sides under stovaine anæsthesia. Recovery was uneventful, and on discharge the urine had a sp. gr. of 1020 and $1\frac{1}{2}$ parts per 1000 albumin. The patient has been very well since, has only slight albuminuria ($\frac{3}{4}$ per 1000), a normal blood pressure, and excellent renal efficiency by the phthalein test—58 per cent. in the first and 25 per cent. in the second hour.

The experience gained from this patient suggests that in some cases there is a hypersensitiveness of the kidneys acquired in the course of a renal inflammation towards the exciting antigen, which may be reduced by small doses of vaccine. On the assumption that the intestinal tract is the original source of bacillary infection, immunisation by the oral route appears a logical procedure, following the observations of Besredka[6] and other French workers. The immediate response to such treatment shown in the next case (Chart 5) suggests that the dissolved antigen in the vaccine may be responsible, as has been shown by Perlweig and his co-workers to exist.[7]

This patient, a boy of 15, had been ill three months with severe nephritis. On admission there was extreme œdema with ascites and double hydrothorax. Only 250 c.cm. were passed daily, the sp. gr. was 1031, and the albumin content 18 and 20 parts per 1000, as measured on two separate occasions. Microscopically the casts were mostly of the granular variety, some being of large diameter. There were few free cells and not many embedded in the casts. On account of the swelling of the genitals a catheter was passed with difficulty and the specimen only yielded a growth of staphylococcus which appeared a simple contamination. The Wassermann was negative. The abdomen was tapped the day after admission and 2200 c.cm. withdrawn, but no benefit to the renal condition ensued during the following week. A small dose (10 millions) of the vaccine used as a substitute in the preceding case was then given by mouth. The result was immediate. Diuresis was established and next day the urine contained but a trace of albumin.

Considerations of space prevent reference to other cases which showed satisfactory results from this treatment. Of special interest is the favourable action of stock vaccine in some chronic renal cases when bacilli were not found in the urine.[1] It would appear that kidney disease may be kept up by absorption of toxins from the intestine without excretion of bacilli being detected. The suggestion that the vaccine acts as a simple diuretic is negatived by its failure to influence the output of urine in non-renal cases when used in similar doses.

Summary.

The onset of acute or subacute nephritis in Egypt is commonly preceded by intestinal infection. Bacteriological examination of the urine in such cases shows the presence of bacilli of intestinal types. These bacilli are capable of reproducing nephritis in laboratory animals. Cure of an intestinal lesion was found to benefit a consecutive nephritis. Vaccine treatment was frequently successful in these cases of infective nephritis. The dose should be inversely proportional to the severity of the renal symptoms. The oral administration of vaccine was found efficacious.

RESPIRATORY CATARRH IN CHILDREN.[1]

BY RICHARD C. CLARKE, O.B.E., M.B. BRISTOL,
M.R.C.P. LOND.,
HON. PHYSICIAN, BRISTOL ROYAL INFIRMARY; HON. PHYSICIAN, COSSHAM MEMORIAL HOSPITAL; HON. PHYSICIAN, BRISTOL ORTHOPÆDIC HOSPITAL.

THE catarrhal child has received far too little attention, and though common enough in all classes its frequency is not sufficiently realised. It may be that until we started to examine in a routine manner so-called healthy infants we saw few cases; the doctor was not called in except for acute bronchitis or broncho-pneumonia, and the consequences, or rather the beginnings of catarrh in children, were overlooked.

The first surprise that I had when conducting routine examinations in young infants, 3 to 6 weeks old, was to note that at least half of them already had respiratory catarrh. I have been through the last thousand of my case-sheets and find that 499 were already infected. On questioning the mothers the usual answer was "Yes, 'e was born with it." The percentage of affected seems very high, but it must be remembered that the patients were drawn from the lower social strata of the population.

The signs on which the diagnosis was based in this series were: (1) Snuffles; (2) sucking in of the lower ribs (Harrison's sulcus); (3) definite bronchial catarrh, found by auscultation.

Before examining the reasons for this extensive infection of the respiratory tract in early life, the effects, immediate and remote, arising directly or indirectly from it, may be noted; some of them are from direct observation, and some of them may be classed as hypotheses.

(1) *The Nose.*—The first thing that happens when an infant gets a cold is that the nose becomes wholly or partially blocked. One effect of this is that the whole respiratory mechanism gets thrown out of gear, owing to the amazing efforts that a young child makes to breathe through a blocked nose, and its reluctance to breathe through its mouth. Anyone can observe this by holding the nostrils of a very young infant. After several unsuccessful efforts to breathe through its nose it wakes up and cries and then, but not till then, will air enter the chest. This nasal obstruction from catarrh leads immediately to sucking in the lower ribs, and to the formation of what is known as Harrison's sulcus. Tradition and the text-books attribute this sign to rickets, but it is so often seen in non-rickety babies, indeed, as a permanent deformity in infants too young for rickets. Rickets may, when combined with nasal obstruction, help to exaggerate and fix the deformity, but the disease has, in my view, nothing to do with its original formation.

The next serious effect of partial nasal obstruction is the difficulty of feeding. Modern opinion attributes the failure of breast-feeding, when it occurs, to the baby and not to the mother. It is thought that all women are potentially good milkers, but that some babies are bad suckers, and that the milk ceases from lack of stimulus. In such cases there is no more potent cause of inadequate sucking than partial or complete nasal obstruction, and where the result—a too frequent one—is failure of the milk-supply, a disaster occurs of the first magnitude in the poorer classes.

The earlier the infant suffers with nasal catarrh, the longer the complaint takes to clear up; in fact, in the majority of instances it never clears up entirely, but becomes more or less chronic with acute exacerbations. And the results of chronic nasal catarrh as the baby grows up are serious; probably it is the one and only cause of the disease known as "tonsils and adenoids." This is to adopt the view that chronic enlargement of the pharyngeal and faucial tonsils is merely one manifestation of chronic nasal catarrh, the condition being the effect of infection of the upper air passages renewed and re-renewed. Another result is chronic suppurative rhinitis with mal-development of the nasal passages, leading to chronic sinus troubles and all their complications and sequelæ.

---

[1] An address given to the Bristol Medico-Chirurgical Society.

An indirect result of bad nasal catarrh in infants, especially if combined with sore buttocks and failure to gain weight from the feeding difficulty, may be a mistaken diagnosis of congenital syphilis, for snuffles, napkin rash and malnutrition, give a fairly complete picture of that disease.

(2) *The Ears.*—Among the hospital class, discharging ears in infants are sadly common. In fact, the medical officer is seldom told of it, as it is regarded as an inevitable concomitant of teething and of no real importance. It generally clears up quickly and relapses with every fresh acute exacerbation of the catarrh. It is not unreasonable to consider that the otitis media of school-children is generally a relapse, a supposition which explains the fact, with which all of us are familiar, that the vast majority of the out-patient class are deafish—to put it mildly. Histories of previous infantile attacks of otitis media are difficult to get, but often I have had the experience of the mother denying a previous attack, when I have had the previous occurrence noted.

(3) *The Chest.*—The following may be rather a surprising statement, but every baby that I have examined under 4 weeks old, and it is something over 400, that has had nasal catarrh has had definite signs of bronchial catarrh. In fact, in almost a majority, the bronchial catarrh is the plainest feature of the disease; the nasal catarrh may not be obvious, though the mother will generally have noticed it, but the tell-tale sucking in of the lower ribs is present.

A few infants from 4 to 6 weeks old escape bronchial catarrh with a cold, but after the age of 3 months this is usual. In only two cases have I noted it after 6 months in a chest previously clear. It would appear that every day of its life that one can put off the inevitable cold in an infant, the more remote becomes the chance of infection of the lower respiratory tract. Under 3 weeks of age the infection is a certainty, but every week after decreases the risk, which is negligible after 6 months of age.

Once a child is bronchitic, every fresh cold, in the words of the nursery, "flies to its chest" and causes an exacerbation of bronchial signs and symptoms. In fact, there is many a child of under 6 months that one would describe as a chronic bronchitic.

As these children grow up the acute attacks continue, though in the intermissions there are always signs in the chest, if they are carefully listened to. If we watch such an infant week by week we find signs either of chronic or acute bronchitis always. I have not watched these children yet beyond 5 years old and only a few up till then, but I submit that the process probably goes on, if to a less degree, through school life, and it is not an improbable speculation that the bronchitic baby is the precursor of the bronchitic school-child and that the bronchitic child is father to the chronic bronchitic adult. As far as I am aware, this has not been suggested before, and one observation in its support is that on the pensions boards nearly every ex-soldier pensioned for chronic bronchitis shows a well-marked Harrison's sulcus, as a fair proof that they were catarrhal babies. This idea that the catarrhal bronchitic baby is the sole ancestor of the chronic bronchitic is speculative, but it is worth following up. The proof of it presents difficulties in the adult, as infantile histories of bronchitis are hard to obtain with any accuracy.

There are at any rate very severe handicaps to the bronchitic child, for attacks of broncho-pneumonia occur with frequency, while measles, whooping-cough, and even the administration of an anæsthetic present added risks to such a child. From these clinical observations one main deduction may be drawn; it is that the earlier in life and more frequent the attacks of catarrh on the child occur, the more damage do they do and the more disastrous is the result.

The question of the pathogenesis is bound up with the factors which control the spread of infectious disease and with the local and general immunity. The position is well put out by Dudley,[2] and I am in entire agreement with his views as expressed.

The development of respiratory catarrh probably depends on two main factors: (1) The number and virulence of the catarrhal organisms which attack the mucous membrane; (2) the local resistance of the mucous membrane and the general immunity of the body.

It is probable that a given mucous membrane can deal with a given number of organisms in a given time—it can deal with x organisms per minute, the value x depending on the virulence of the organism and the resisting power of the mucous membrane.

An individual with a catarrh breathes out organisms suspended in particles of moisture very much in the same way that a person breathes out smoke when smoking tobacco. That is, as the smoke leaves the mouth there is first a concentrated puff and then it gradually disseminates into the room where, in the absence of proper ventilation, it hangs about the room. So it is with a person suffering from a respiratory catarrh. The concentrated breath is highly charged with organisms, which in the absence of proper ventilation will gradually diffuse throughout the room. On this theory then, one can get the $x+1$, the morbid dose, either by a direct hit from a cough, sneeze, &c., or by staying too long in an atmosphere too heavily loaded with organisms. This has been proved by exposing plate cultures in such circumstances. This morbid dose, this $x+1$, is determined by the virulence of the organisms and the local and general resistance, but the local resistance, the mucous membrane, must be the main barrier to catarrhal infection. That the mucous membranes have local resistance has been proved by A. Fleming.[3] Apart from the possibility of chemical disinfectants, he has shown that the mucous membrane secretes a definite bacteriolytic agent. What would appear from clinical observations is: (1) that the very young mucous membrane is deficient in resistance; (2) that the mucous membrane, which has been the object of early and repeated attacks, either loses or never acquires an adequate resistance.

The view that the general immunity of a very young baby is less than that of its mother is not generally held, but there is a good deal of clinical evidence to support the theory by analogy that the local resistance is deficient. For instance, the intestinal tract is notoriously easy to infect in the young infant, and the skin is extremely susceptible to staphylococcal infection. In the respiratory tract the frequency of catarrh under 3 weeks old, the undue chronicity of it when it does occur, and the rapid spread into the lungs under 6 weeks old affords considerable proof of early local deficiency. And pathological attacks of catarrh on these mucous membranes, respiratory and intestinal, do not confer immunity but rather the reverse. The ideas of Prof. Kenelm Digby, of Hong-Kong ("Immunity in Health," 1919), are to my mind correct—a normal child acquires its local, and in part its general resistance to catarrhal organisms, by frequent submorbid doses of these organisms. But morbid doses—that is to say big enough doses to cause an inflammatory reaction, do not confer local immunity, but cause more or less permanent damage to the epithelium of the respiratory mucous membrane. This would be true whether respiratory catarrhs are caused by well-known catarrhal organisms, or whether some unknown filter-passer is the "villain of the piece."

In the prevention of this condition these theoretical views become of extreme importance. The morbid dose of catarrhal organisms on the respiratory mucous membranes—what may be styled the "knock out" dose—must be postponed as long as possible. There can be no fear of the child missing the submorbid or immunising dose. This postponement may seem impossible to secure among the badly housed lower stratum of the population, though among the decently housed and not overcrowded class it is fairly easy. We have the two things to aim at—viz.: (1) to avoid what has been styled the direct hit, and (2) to keep an infant out of stuffy places.

---

[2] THE LANCET, 1924, i., 1141.

[3] Proceedings of the Royal Society, 1922.

To avoid the direct hit attention must first be devoted to the mother. If she suffers from chronic suppuration of the upper air passages, it will be difficult, but antenatal nasal hygiene and treatment should be carried out. If she has the misfortune to have an acute catarrh when the baby is born the direct hit may be avoided by instructing her to wear a folded handkerchief over the mouth and nose while " doing " or feeding the baby. My personal experience of the value of this precaution has been most satisfactory, and it should be extended to the maternity nurse and children's nurse. All persons coming to view the infant should be inspected for colds and shut out if a cold is admitted, and always be requested neither to breathe on or kiss the baby.

To avoid the other main method of infection, the germ-laden atmosphere, is an easy matter in an uncrowded house. The infant should either be kept out of doors or in a draught. It is difficult to overcome prejudice in this matter, especially during the daily bath, but it is certain that no infant can come to any harm if efficiently bathed in front of a fire with all the windows open. How often is this rite performed in the complete absence of ventilation, with steam on the windows and in the presence of admiring, but highly infectious grandmothers and aunts.

Thus far for the more fortunate classes, but with overcrowding and housing difficulties among the less well-to-do, we have a more difficult problem. But much may be done, though, if an intelligent mother uses the mask, keeps the baby in a cot under the open window, and keeps it during the day time either out of doors or in her bedroom opposite the open window, as opposed to the stuffy kitchen.

The almost insurmountable difficulty is the parent, nurse, or other children who are what may be termed carriers—i.e., suffer from chronic respiratory catarrh. The position recurs again and again of the catarrhal mother with the catarrhal child, and I am convinced that by far the most potent cause of recurring catarrh, leading to chronic bronchitis and enlargement of the tonsils and adenoids, is infection from some one in the house renewed and re-renewed. It is possible to argue that heredity plays a part, but I do not believe it myself. It is just as frequently caused by an infected nurse. If the parents are infected prophylaxis breaks down. A nurse can be got rid of, but a mother cannot be done away with. Treatment, and the use of the mask, is the only possible method. For the rest, children should be kept away from people with colds and children's parties should be cut down to a minimum and—I want to lay stress on this—kept in a draught. Anyone who has closely observed children will agree that as far as their personal comfort goes, cold does not count.

The treatment of the catarrhal child is the prevention of fresh infection, after affected lymphoid tissue, if present, is removed. The longer that such a child can be kept " free from a cold " the more it will resist the next one. Cod-liver oil is a good stand-by.

THE TOXIC EFFECTS OF LEAD ADMINISTERED INTRAVENOUSLY. By Prof. W. BLAIR BELL, Dr. W. R. WILLIAMS, and Dr. L. CUNNINGHAM.—Owing to a misunderstanding this paper was printed before corrected proofs were received. The errors will be made good in the reprints which the authors will be glad to supply.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF THERAPEUTICS AND PHARMACOLOGY.

A MEETING of this Section was held on Oct. 13th, Dr. GEORGE GRAHAM, the President, being in the chair. He delivered his presidential address on

Some Difficulties in the Use of Insulin,

and began by recalling the enthusiastic welcome accorded to the new discovery of insulin at a similar meeting two years ago. Insulin had shown itself to be a very potent drug, and its use during the succeeding two years had proved to be attended with considerable danger. It was not a cure for diabetes, but so effective a counter-agent that most patients under treatment enjoyed the best of health, and their condition was only betrayed by the food on their tables. Only a comparatively small portion remained invalids and very few died. With the help of some very instructive statistics he analysed a collection of 85 patients who had been treated with insulin at St. Bartholomew's Hospital. These fell into three groups: (1) those he had personally supervised during the last two years; (2) out-patients under the care of his colleagues since January of this year; and (3) earlier patients whose after-history had been followed up. Of these, 17 had died with various symptoms, such as vomiting, pyrexia, blood poisoning, cerebral hæmorrhage, or coma. Some had refused the diet ordered. The deaths mostly occurred outside hospital, and in 12 cases there was evidence of some other disease, such as influenza, which had precipitated the fatal issue. One case, which died in hospital, had been discharged once and subsequently returned. It was fairly certain that she had not taken the prescribed diet at home; when she came back to the ward it was found that her insulin requirement had increased from 10 units to 110. She had no signs of sepsis except a discharge from the ear. She was given 100 units in the course of 15 hours, became comatose, and died after 18 hours. At the post-mortem nothing abnormal was found except that the pancreas was smaller than usual with fewer islets. The staining reactions were not quite normal but seemed to be healthy. It seemed certain that in this case there was a progressive degeneration of the islets of Langerhans which insulin was powerless to prevent; indeed, the injections given precipitated the coma.

Home Treatment.

The two difficulties encountered in treating patients at home after discharge from hospital were the estimation of the blood-sugar and the regulation of diet and insulin dose so as to keep it normal. He believed it best for the patient to maintain the percentage of sugar within normal limits if possible, although he had had cases do well with a persistently high blood-sugar. He aimed at keeping the morning value below 0·13 per cent., but the dosage of insulin required must not cause discomfort to the patient and the sugar should be kept down without insulin as far as possible. The sample of blood for estimation should be taken between 10 and 12 A.M. after an ordinary breakfast, and should not be preceded by any fast or insulin. A blood-sugar which was normal at 10 o'clock had often risen by noon, and the variation gave a rough idea of the patient's power of resistance. A high blood-sugar meant a low resistance. In some cases the blood-sugar would come down without any apparent reason and in others rise equally inexplicably. The usual dose for mild cases was 15–30 units a day, and one dose only should be given if this was possible. If a patient developed a high blood-sugar he should be instructed to raise his morning dose by 2 units at a time until the percentage fell again, but in some cases this increase might cause signs of overdose at midday without lowering the percentage in the morning sample. Sometimes two small doses instead of one large one overcame the difficulty, and to these patients an evening dose might be given. Some people, indeed, seemed able to take a bigger dose in the evening than in the morning, though usually he advised them to keep the evening dose smaller than the morning one in case hypoglycæmia should occur during the night. The speaker showed the chart of a boy of 9 years of age in whom 4 units produced at first symptoms of overdose. He had pyrexia, and a tuberculous lesion in the larynx was discovered. It was probable that he had a subacute infection of the lungs also. He was discharged from hospital in January with the blood-sugar normal. In October the blood-sugar rose and the insulin was proportionately increased. In the following January it rose again, but a further increase in the morning dose of insulin produced no effect. When, however, the evening dose was increased the percentage was controlled, and after ten months the child was still doing well. He was now having 6 units in the morning and 8 in the evening, and his diet represented 1705 calories (carbohydrate, 25; protein, 94; fat, 130). Possibly the evening dose was required to counteract the pyrexia, which tended to raise the blood-sugar.

Spacing of Doses.

Two patients under his care showed symptoms of overdose every time their insulin was increased. One woman was having an interval of only eight hours between doses, another of nine hours. The symptoms in both cases disappeared on increasing the interval to 11 and 13 hours respectively, and it was then possible to increase the insulin dosage. Patients should be warned against the danger of hypoglycæmia, but it had only occurred in two of his cases, one of whom became unconscious and the other hemiplegic. Both recovered when sugar was given, and after that it was found that the insulin requirement had decreased.

Infections.

Minor infections had the effect of raising the blood-sugar. His present practice was to increase the dose by 1 to 3 units directly a minor infection, such as a cold in the head, showed itself. It was too soon as yet to report the results of this method. Sometimes such infections were followed by a drop in the insulin requirement. When a major infection occurred the insulin dose should be increased immediately and courageously. Sometimes a patient who had been receiving 20 units might have to be raised to 200. The urine should be collected every three hours and tested for sugar, the large dose being continued until the sugar content dropped. Then the insulin was immediately stopped and none given until the sugar in the urine began to rise again. The danger came with convalescence, as hypoglycæmia was liable to supervene when the temperature dropped. Sugar must be kept ready for such an emergency.

Relation between Insulin and Exercise.

Dr. R. D. **LAWRENCE** spoke of the very marked effect of exercise in decreasing the blood-sugar, which was especially noticeable in people who constantly alternated between sedentary and active pursuits. Hard exercise might produce severe hypoglycæmia. He mentioned the case of a gardener whose diet had been constant for 18 months. Last winter his regular insulin dose was 10 units in the morning and 6 in the evening, which kept a good balance, his blood-sugar falling to 0·1 four hours after the dose. About May he started to work very much harder and also took up cricket; after one week he suffered from dizziness caused by hypoglycæmia, and in July he was keeping a good balance with 6 units once a day. At the end of that month he stopped work and cricket and his blood-sugar went up. He restored his balance with 8 units in the morning and 5 at night. Following medical advice he returned to work and found that 5 units daily were then sufficient. He now carried out urine tests nearly every day and had learned to adjust his own insulin to correspond with his activities. Another patient of sedentary habits, who had been receiving 16 units in the morning and 12 at night, suffered from hypoglycæmia two or three hours after his Sunday tennis if he had more than 10 units in the morning; 8 kept him in good condition. He went on a vigorous holiday, and for three weeks was able to double his carbohydrate intake on the same insulin dose without passing sugar. He even suffered from hypoglycæmia if he took exercise before meals. This exercise factor would account for the apparent improvement of patients on their discharge from hospital and return to active life.

Dr. Lawrence showed a very interesting chart illustrating the effect of intensive exercise on the blood-sugar after a measured meal compared with the blood-sugar if no exercise were taken. Diets were more difficult to alter, however, than insulin doses. His practice was to teach the patients to treat themselves by diet as far as possible and to increase the insulin dose, when this became unavoidable, by 2 units morning and night. All his cases had returned to normal life and on the whole were taking less insulin than Dr. Graham's, the average being 15 units in the morning and 10 at night. Some, especially coma cases who had recovered, started on 25 in the morning and 20 at night. The uniform diet he used tended to produce a uniform insulin requirement. He had had no cases of infection in the patients who were attending regularly, except for colds in the head and influenza, which had only produced glycosuria in one case.

Dr. E. P. **POULTON** showed an interesting chart made by a patient himself showing blood-sugar variations and Rotherer reactions side by side, the latter giving a more sensitive indication of his condition. He thought that mild cases did better with small doses of insulin combined with dieting than with dietetic measures alone. He quoted the case of a medical man who had had diabetes since 1906. His attacks of giddiness increased in severity in 1922, and he entered hospital and found that small doses of insulin made a great difference to him. After a month the insulin was dropped and the improvement was maintained without it. In very wasted patients insulin was dangerous without carbohydrate. He had had the same experience as Dr. Lawrence that the insulin requirement of patients tended to settle to a common level.

Dr. C. H. **BEST** (Toronto) said that the problems encountered in the birthplace of insulin were just the same as those of this country. Out-patients who attended regularly did very well, but the irregular ones caused difficulty, so much so that a special social service department had been organised at the Toronto General Hospital to keep in touch with these cases. He agreed with the President on the danger of infection and regarded it as the greatest bugbear of the clinician. There seemed no solution of the problem except early recognition and counter-action by an increased dose of insulin or modification of the diet. The path of those who did not contract infections was smooth. The first person ever to receive a dose of insulin, a lad named Leonard Thompson, was now a healthy young man. Dr. Lawrence's experiences were just what he would have expected.

Insulin in Children.

Dr. G. A. **HARRISON** spoke of the special difficulties of treating diabetic children. Since it was essential to give a diet of sufficient calories to permit growth the food intake had to be large. The difficulty was, therefore, to keep pace with these comparatively rich diets without giving too much insulin. Several American writers maintained that one injection daily was sufficient unless the dose exceeded 10 units, when it had better be divided into two or more. In several cases where large doses were necessary three or four doses were given daily before meals, and another at midnight. The multiplication of doses, however, was extremely bad for children, partly because of the hardening effect on the skin and partly because of the alarm caused to the child by the whole process of injection. In fact, parents were often unable to give the insulin for this reason. The maximum number should therefore be reduced to two if possible, but severe cases tended to show a rise in the blood-sugar after a night's rest. With careful spacing of meals, however, and a 10- or 12-hour interval between doses the blood-sugar could often be kept down. Parents should be told to supervise the exercise of the children in order to prevent a sudden drop in blood-sugar from this cause. In children intercurrent sepsis was liable to be very sudden and serious. The prescribed diet was very difficult to give when the child was sickening for some infection and the doctor, hearing that all the food was not being taken, was liable to fear hypoglycæmia and reduce the insulin. Unless he could test the blood-sugar often it was difficult to recognise the true cause of the anorexia. Insulin should never be stopped entirely, even if no food were being taken at all, as a patient suffering from an acute illness might have a large carbohydrate store. The family doctor must strike a balance between the factors of increased requirement and decreased tolerance. It was far better to send the child to a nursing home, but in the interval he might as a general rule substitute milk for the prescribed diet, as it was the only food most sick children would take. If the normal dose of insulin were 10 units it should be reduced to 5; if over 10, then two-thirds of the usual dose should be given. Sugar should be kept handy, but insulin should never be given at the same time as glucose. After 24 hours, when the glycogen stores were depleted, a little might be given. The hypoglycæmic reactions of children were not so marked as those of adults; often an attack started with fretfulness and then the child became quiet and pale. It was naturally extremely difficult to distinguish these signs from those of pyrexia. He summarised the difficulties as inverse to the facilities for blood-sugar estimations.

High Blood-sugar a Mendelian Recessive.

Dr. P. J. **CAMMIDGE** remarked that it seemed to be assumed that all forms of diabetes were essentially the same. In his opinion there was a vital difference between the adult and the childish form. Juvenile diabetes had a distinct ætiology and origin. He had recently undertaken some research which would indicate that a constitutional high blood-sugar was a Mendelian recessive character. An animal with high blood-sugar produced a normal progeny, but the offspring of these showed a Mendelian proportion of individuals with high blood-sugar. Mice illustrated this principle very clearly and probably other animals would also. If it was, as he believed, a true Mendelian recessive it would almost certainly appear in man as well. He had come to the conclusion that there was no such thing as a normal blood-sugar, but that individuals varied between wide limits. Low blood-sugar might also be recessive, but the experiments on this were not yet complete. The theoretical reason for these results lay in the interaction of the endocrine secretions. Definite chemical experiments had proved that insulin and adrenalin had opposite effects upon the activity of certain glycogen ferments. Insulin and pituitary extract, on the other hand, did not have opposite effects but chemically neutralised one another. Excessive doses of insulin therefore tended to exhaust the pituitary and set up diabetes insipidus in a mild form. Another influence in elderly diabetics was hyperthyroidism. There was no activity between thyroid and insulin, but the thyroid activated the adrenalin which opposed the insulin. If the thyroid were diminished by diet and treatment signs of overdose of insulin tended to appear.

A great deal of difficulty arose from always doing tolerance tests with sugar. It was rapid and easy, but people ate other things besides sugar, and much truer results were obtained from testing after an ordinary mixed meal. Another source of error was the practice of giving insulin half an hour before a meal and making the tolerance test three-quarters of an hour after. By this method the maximum of insulin reaction was reached considerably before the maximum food reaction, especially in hypothyroidic patients. If the insulin were given earlier, say an hour or an hour and a half before the meal, the maxima would be more likely to coincide.

NEWCASTLE-UPON-TYNE AND NORTHERN COUNTIES MEDICAL SOCIETY.

THE first meeting of the session was held in the Royal Victoria Infirmary, Newcastle, on Oct. 8th, when Dr. **NEIL MACLAY** delivered his inaugural presidential address on

Modernism in Medicine.

As an observer of medical life for 30 years he had been able to view it from two different standpoints. First as a general practitioner, and later from the somewhat narrower sphere of a specialist. This had been a period of great changes and advances in medicine, but nevertheless there were disquieting signs of retrogression. On all sides there was a steady growth of superstition, both in religion and medicine, and an inclination on the part of the public towards quackery. Dr. Maclay went on to deal with the part which medical men might play in combating these influences. The crowded curriculum of the student intensified the difficulties. As a result newly qualified men seemed to be now less able to judge what was commercial quackery and what scientific truth.

Exhibition of Clinical Cases.

Mr. J. S. **ARKLE** showed various ophthalmic cases, the chief of which were (1) a recent extensive hæmorrhage into the vitreous in a woman of 24, seven months pregnant; (2) ruptured choroid following concussion; (3) a severe neuro-retinitis with well-marked "star" figure at the macules, in a patient without any obvious cause.

Mr. **JOHN CLAY** showed a man, aged 36, from whom he had removed an astragalus 16 years earlier after an injury. Since then the man had been able to serve as an infantryman in the Army and pursue heavy work regularly.

Dr. **HORSLEY DRUMMOND** showed a case of aortic aneurysm with dislocation of the inner end of the clavicle; also cases of mediastinal tumour and subacute combined degeneration of the cord.

Dr. H. E. **GAMLEN** demonstrated various radiological films.

Dr. W. E. **HUME** showed a case of erythræmia in a man of 48, where the symptoms had started six months earlier with hæmoptysis; also cases of crossed paralysis from pontine softening and auricular fibrillation treated with quinidine sulphate.

Mr. C. G. **IRWIN** showed a case of extensive syphilitic osteitis of the skull which appeared in spite of previous antisyphilitic treatment.

Dr. F. J. **NATTRASS**: A case of myasthenia gravis; a woman of 26 with weakness of palate and external ophthalmoplegia.

Dr. A. **PARKIN**: A case of tuberculous spine with pressure myelitis in a child, and cases of different types of aneurysms.

Mr. F. C. **PYBUS**: A case of trigeminal neuralgia successfully treated by operation; also cases of axillary aneurysm and congenital dislocation of the hip.

Mr. R. J. **WILLAN** demonstrated a group of cases with pyelographic records which illustrated the value of pyelograms in localising and differentiating kidney lesions. These were congenital cystic kidneys in an adult woman; a woman with right-sided pyonephrosis; a case of left-sided hydronephrotic kidney.

Reviews and Notices of Books.

TEXT-BOOKS OF MEDICINE.

Taylor's Practice of Medicine. Thirteenth edition. By E. P. POULTON, M.D. Oxon., F.R.C.P. Lond., Physician to Guy's Hospital; formerly Radcliffe Travelling Fellow and Beit Memorial Research Fellow. With the assistance of C. PUTNAM SYMONDS, M.D. Oxon., F.R.C.P. Lond., Assistant Physician for Nervous Diseases, Guy's Hospital; formerly Radcliffe Travelling Fellow; and H. W. BARBER, M.B. Camb., F.R.C.P. Lond., Physician-in-Charge of Skin Department, Guy's Hospital. London: J. and A. Churchill. 1925. With 48 plates (8 coloured) and 93 text-figures. Pp. 1063. 28s.

Dr. E. P. Poulton has again produced a revised edition of the late Sir Frederick Taylor's famous text-book. The extent of revision rendered necessary by the advances of medical science may be gathered from the fact that new articles have been added dealing with meliodosis, tularæmia, ectoscopy, manganese poisoning, Mönckeberg's degeneration, the recent work on the ætiology of cancer, and half a dozen other subjects, whilst the authors have had to rewrite or largely revise their previous articles on anaphylaxis, jaundice, pernicious anæmia, the spleen, cerebro-spinal fluid, epilepsy, and many other equally important topics. In addition to these revisions and amplifications, there are several new features which call for special comment. In the first place, Dr. Poulton has seen fit to introduce at the end of each section a list of important references, with numbers corresponding to places in the text. In this manner he has not only eliminated from the text many unnecessary quotations, but he has provided for his readers a selected bibliography most useful as a guide to further reading at a time when medical literature has become so ponderous. The illustrations too in the new volume have undergone considerable improvement. A generous provision of radiograms enables the student to make a proper study of this increasingly important aid to diagnosis. The eight new coloured plates include excellent illustrations of normal and abnormal leucocytes. It is perhaps open to question whether the plate of nucleated red cells facing p. 520 is of sufficiently common interest to merit inclusion. If so, it requires more detailed explanation than is at present to be found in the text.

A survey of the text confirms a previous impression of accurate and scholarly writing. Those who are not reading the book from cover to cover would do well to turn to Dr. Poulton's articles on asthma, diabetes, pernicious anæmia, and peptic ulcer. Laboratory tests are given their proper place, although it is curious to see so little stress laid on frequent measurement of the specific gravity of the urine as an index of renal efficiency. Yvon's method of estimating blood-urea is given preference to the more useful analytical methods of Folin. The section dealing with diseases of the central nervous system has again been written by Dr. C. Putnam Symonds, who has revised or rewritten the articles dealing with examination of the cerebro-spinal fluid, neuritis, cerebral diplegia, epilepsy, and several others. New and excellent photographs illustrate the topical diagnosis of lesions of the cord by means of lipiodol injections. The section, while it contains only what is necessary for the use of students and practitioners, achieves a high standard. The full description of rheumatic chorea included in this section might with advantage be transferred to the chapter on rheumatic fever. Dr. H. W. Barber once more deals with the diseases of the skin, and this section, too, is now enriched with coloured illustrations to its countless benefit. This section of the book has always been well done as far as that was possible without pictorial help. The illustration of psoriasis facing p. 939 might be improved. Dr. Barber has adopted the classification of Dr. Darier, to whose famous book he acknowledges his indebtedness, but the section as it stands bears the stamp of Dr. Barber's own extensive experience and learning.

To have accomplished all this within three years of the previous edition is a tribute not only to the learning and industry of Dr. Poulton and his collaborators, but also to the deserved popularity of the work among students and practitioners.

A System of Clinical Medicine. Seventh edition. By THOMAS DIXON SAVILL, M.D. Lond. London: Edward Arnold and Co. 1925. Pp. 1004. 28s.

THIS carefully planned text-book dealing with disease from the standpoint of symptomatology was first published over 20 years ago, and may now be said to have established its position as a modern classic. Since Dr. Savill's death in 1910, just after the publication of the second edition, the task of keeping the subsequent issues up to date has been ably performed by his widow, Dr. Agnes Savill. The seventh edition has in considerable part been rewritten and fully revised, though in bulk the volume has increased by some 50 pages only; for assistance in this labour Dr. Agnes Savill expresses her indebtedness to Dr. Harry Campbell, Dr. J. Strickland Goodall (Diseases of the Heart), Dr. J. D. Rolleston (Fevers), Dr. S. W. Patterson (Diseases of the Stomach and Liver), Dr. Angus MacGillivray (Diseases of the Eye), Dr. Robert Cole (Mental Diseases), Sir James Dundas-Grant (Diseases of Ear), Mr. Philip Franklin (Diseases of Nose and Throat), Colonel W. S. Byam (Tropical Diseases), Prof. Louise McIlroy (Diseases of Women), Dr. Skene Keith (Immunity), Dr. Leonard Williams (Thyroid Gland), Dr. Langdon Brown (Diabetes Mellitus), Dr. Gordon Ward (Diseases of Blood and Spleen), and Dr. V. E. Sorapure (Basal Metabolism and Animal Measurement). Dr. Thomas Savill's plan of designing a text-book of medicine "from the patient's point of view," was no simple matter to carry into effect, but there can be little doubt that his ambition has been fulfilled, nor is anything neglected in the way of ætiology, pathology, and treatment to make the work complete. Important diseases are indicated by the use of large type, rarities are described in smaller type, and abundant cross references are given to avoid repetition and increase the utility of the book. We can with increasing confidence recommend for the seventh time "Savill's Medicine" to senior students and practitioners on the look-out for a sound summary of clinical diagnosis.

The Principles and Practice of Medicine. By the late Sir WILLIAM OSLER, Bt., M.D., F.R.C.P. Lond., F.R.S. Tenth edition, thoroughly revised by THOMAS MCCRAE, M.D., F.R.C.P. Lond., Professor of Medicine, Jefferson Medical College, Philadelphia. London and New York: D. Appleton and Company. 1925. Pp. 1234–xxxxi. 30*s.*

"The Principles and Practice of Medicine" first appeared over 33 years ago, and those who have read the biography of Sir William Osler by Harvey Cushing will have noted the large part which this text-book took in Osler's life. The value of the book is so well known and universally recognised that it requires no further commendation on our part; in the tenth edition, which has been thoroughly revised by Prof. McCrae, a constant effort has been made to retain the features characteristic of its author, who "felt that a text-book should contain well-established knowledge and not every new wind of doctrine." Since the previous edition which passed through Prof. McCrae's hands there has been a complete resetting of the book, and many subjects which are new or the discussion of which is altered have now been incorporated, among them scarlet fever, car and sea sickness, carbon monoxide poisoning, epidemic diaphragmatic pleurodynia, many tropical and local diseases, hypotension and hypertension, and so forth. Additions have been made throughout to the sections on symptoms and signs, diagnosis and treatment, the aim being to include material which is of established value. This edition will not only maintain but enhance the reputation of its predecessors.

A Synopsis of Medicine. Fourth edition. By H. Letheby Tidy, M.D., B.Ch. Oxf., F.R.C.P. Lond., Assistant Physician to St. Thomas's Hospital; Physician to the Royal Northern Hospital. Bristol: John Wright and Sons, Ltd. 1925. Pp. 1000. 21*s.*

This synopsis was first published in 1920, and the measure of its success may be gauged by the present appearance of the fourth edition, revised and enlarged. The most extensive alterations are in the chapters on diabetes, and have been necessitated by the rapid advance of knowledge since the discovery and use of insulin. The article on jaundice has also been rewritten, and is based on the views of MacNee. Other articles which have been entirely, or almost entirely, rewritten include botulism, visceroptosis, hæmatoporphyrinuria, infarction of the lung, primary purpura, and acholuric jaundice. Considerable alterations have been made in the chapters on gall-stones and bronchial asthma, while that on splenic anæmia has been recast. New chapters have been added on blood diseases of childhood and on thrombosis and embolism. The object of this précis of medicine is to assist those who have to revise rapidly their knowledge of medicine in general or of some disease in particular—the worried student, the general practitioner, or possibly even the teacher—and Dr. Tidy's painstaking work, in fulfilling this purpose, has met with the success which it deserves.

CLINICAL FEATURES OF HEART DISEASE.

An Interpretation of the Mechanics of Diagnosis for Practitioners. By Leroy Crummer, M.D., Professor of Medicine, University of Nebraska. New York: Paul Hoeber. London: Henry Kimpton. 1925. Pp. 353. 12*s.* 6*d.*

The introduction of new methods in diagnosis may temporarily upset the sense of perspective, but in the course of time such methods find their level, which is generally to supplement rather than to replace those which have been previously in vogue. The cardiologist of to-day is fully prepared to admit the extent of his debt to the work and teaching of the great clinicians of the past. Many of their doctrines have stood the test of time, while others have had to be discarded in the light of more recent knowledge; but to restate those doctrines more clearly or more convincingly than they have been stated by the writers of past generations is no easy matter. As his text Dr. Crummer takes a concisely worded document prepared by the American War Department in 1917 for the guidance of medical officers employed in the examination of recruits. He deals in turn with the various important facts which may be elicited in taking the history of a cardiac case, with the different methods of physical examination, with valvular disease, and with other branches of the subject. His views on the components of the first heart sound arising in the right and left ventricles respectively are interesting; but apart from this he adds little to what has been written before. Some of the terms employed, such as the "onward" murmur, are unfamiliar to the English reader. The author appears to take an unduly pessimistic view of the clinical powers of the modern physician when he says that "Even when . . . . obtained or corrected by the most experienced members of the staff . . . . the history is quite apt to be absolutely worthless," or again, that "the discovery of albumin in the urine no matter what the source is called Bright's disease." In the treatment of auricular fibrillation he expresses the opinion that "a sudden reduction in heart-rate to 80 or below indicates overdosage with digitalis." This is over-cautious. In a book of this size it is not possible to discuss the evidence on which statements of opinion are based, and the impression is left that the author has attempted to cover too wide a field.

SURGERY.

Some Encouragements in Cancer Surgery. By G. Grey Turner, F.R.C.S., Surgeon to the Royal Infirmary, Newcastle-upon-Tyne. Bristol: John Wright and Sons. 1925. Pp. 75. 7*s.* 6*d.*

This is an account of a wonderful series of patients with advanced cancer who have been operated upon by the author and who have lived for many years without recurrence or have died only after a long respite of apparent health. As was to be expected, these gratifying results have been obtained more particularly in certain types of growth, or in cancer in certain situations. It is strikingly brought out how successful operative treatment may be in carcinoma coli, and a very remarkable case is the complete cure of a man with a chondrosarcoma of the tibia. There is a certain excuse for the gloomy outlook which prevails in the minds of many surgeons with regard to the operative treatment of malignant disease, but no one could fail to be spurred to increased efforts along recognised surgical lines by reading this book. Mr. Grey Turner has done a great service in recording these results.

Chirurgische Operationslehre. Fourth edition. By Prof. Dr. Friedrich Pels Leusden. Berlin: Urban and Schwarzenberg. 1925. Pp. 832. M.18.

This well-known text-book has an established position which it is likely to retain, for it has been brought thoroughly up to date. It is a rather larger book than the average English student reads, as it is very comprehensive. Many operations which have very seldom been done are described. This is one of the features which add to its value, as also the fact that minor surgical operations are not neglected. It reflects, of course, German teaching; but this does not make it very different from the usual English text-book, for surgical practice all over the world tends increasingly to conform to a single standard. The book can be recommended.

THE EVOLUTION OF ANATOMY.

A Short History of Anatomical and Physiological Discovery to Harvey. Being the substance of the FitzPatrick Lectures delivered at the Royal College of Physicians of London in the years 1923 and 1924. By Charles Singer, M.A., M.D., F.R.C.P. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1925. Pp. 209. 12*s.* 6*d.*

Dr. Singer in his two courses of lectures has set forth in a pleasing and scholarly manner the growth of anatomical, and to some extent of physiological, knowledge. He begins with allusions to the dawn of anatomical ideas as exemplified in drawings of animals from the Magdalenian caves and by a model of an arm from Knossos, and then passes in rapid review such knowledge of anatomy as was exhibited by Assyrians, Egyptians, Greeks, and Romans. He includes the great poem of Lucretius under the head of Latin anatomical literature, but we cannot agree in his dictum that "as an observer he (Lucretius) is negligible." Of course, he occasionally made gross mistakes, but his observation of ordinary natural phenomena was singularly acute, a fact which every commentator has noticed. In his section upon mediæval anatomy Dr. Singer refers to a drawing in an MS. of Guy de Vigevano preserved in the Musée Condé at Chantilly, representing a dissection, and remarks: "The relation of the dissector to the subject in this and other miniatures of the same MS. shows that the body was suspended." Dr. E. Wickersheimer, however, in his paper on the same MS., published in the *Archiv für Geschichte der Medizin*, 1913, considers that the upright position was a traditional method of representation and probably originated from the fact that in this position it was far more easy to show the action of the surgeon in making incisions. Almost the entire latter half of the book is devoted to Vesalius and Harvey, whose researches are described with a simple clarity worthy of imitation by other writers who may feel inclined to discuss similar matters. Dr. Singer concludes by reminding his readers that William Sharpey, the first holder of the first chair of physiology established in England, was himself a student of Padua.

A TEXT-BOOK OF OARSMANSHIP.

By GILBERT C. BOURNE, Secretary of the Oxford University Boat Club, 1884 and 1885. Oxford University Press. 1925. Pp. 376. 18s.

THE author has carried for so many years a name of such weight among those who are experts in rowing, judges of its art, and instructors of famous crews, that his considered opinions, after 40 years' experience of Oxford oarsmanship, are entitled to respect. This work began as an essay written in undergraduate days; the author was firmly established in correct principles by the celebrated Dr. Warre while at Eton, so that the book contains the conclusions of a lifetime's study of the subject. It deals in order with the theory of rowing, the art of rowing, oars and boats, coaching, and muscular action in rowing. It is with the last of these sections that we are called upon to deal particularly. These chapters do not pretend to be written for the anatomist, but they seem to be admirably suited to the purpose the author has in view. An intelligent oarsman, especially if supervised by a coach who has good knowledge of and belief in the value of the subject, ought to find these anatomical details of great use to him in his effort to understand how the greatest amount of work may be got with the least expenditure of effort. The short accounts of muscles and their actions are correct and excellent, and sufficiently full to present a picture, while the figures in the text are clear and good; it may be pointed out that the coraco-brachialis is wrongly labelled in Fig. 48. Attention should, however, be called to the common but mistaken notion that the humerus and scapula move at different times when the arm is raised above the head, for the swing forward is essentially an act of raising the arms above and in front of the head. The analysis of the act of raising the arm, recognising the necessity of fixing the scapula, thereafter speaks of the raising of the humerus on the fixed bone, and of the amount of upward raising made possible by the additional rotation of the scapula; but it must be understood that the two motions are not consecutive but concurrent. The scapula begins to move at the same time as the humerus, although more slowly, and its movement continues throughout the greater part of the raising of the arm. In other words, the scapula is overfixed from the beginning, affording in this way a point d'appui for the action of the humerus. In this complex the trapezius acts alone at first and the serratus magnus comes in automatically at a certain point; it cannot be brought in before this, and the trapezius cannot by itself manage the whole affair. The lower fibres of the trapezius are mainly concerned, the middle fibres coming in toward the end of the movement to give the final touch to the scapular action. The upper fibres have little to do beyond giving active support, and it seems not improbable that the contracted condition of these fibres observed at the end of the forward swing, in overreaching, or even in turning the oar off the feather, may be really associated with an effort to lift up the head. We have laid some stress on this because an appreciation of its bearing may lead to modification of some of the theoretical views advanced by the author when dealing with the movements concerned; but it is naturally impossible to be sure of what does take place, exactly and fully, and in practice it probably matters little whether the teacher makes use of the correct description or the correct but misleading analysis. We confess to some doubt about the action of the gluteus maximus, at any rate in the first part of the stroke, but this, again, is of secondary importance, and the chapters on muscular action may be commended for their clearness and practical value.

The rest of the book is of the same high level in exposition and is illustrated by clear and useful diagrams and drawings. The work is, in fact, most interesting; to anyone who has ever handled an oar, however incompetently, it is fascinating. The whole production is of that excellence which we are accustomed to associate with the Oxford Press.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. August, 1925. —W. I. Clark and E. B. Simmons describe their own observations over a period of 14 years upon the dust risk in the abrasive industry, where such artificial abrasives as aluminium oxide (emery) and silicon carbide (carborundum) are made and handled. Results of clinical and X ray examinations are given, together with a statement of the occurrence of pulmonary tuberculosis. The conclusion is arrived at that inhalation of these dusts does not lead to fibrosis, and that the use of artificial abrasive wheels, instead of sandstone wheels, reduces the risk of pneumonoconioses for grinders to an enormous extent. The negative evidence against emery and carborundum here given is of particular importance.—P. K. Thomson reports upon investigation into whether small amounts of zinc from biologic material ashed by the incineration process can be recovered. The volatility of zinc suggested there was considerable risk of losing the metal during incineration. A series of experiments made are carefully described, and the author found that even small amounts of zinc can be easily and safely detected after biologic material has been ashed at 450° C.—A new hazard in industry is reported by W. B. Castle, K. R. Drinker, and C. K. Drinker as occurring among workers employed in applying a luminous paint containing radium. Five cases of necrosis of the jaw were discovered. The necrosis was a chronic progressive condition closely resembling that resulting from phosphorus poisoning. There were opportunities for the paint to be smeared on the fingers and so absorbed through the skin, or even swallowed through the practice of pointing paint brushes in the mouth; but the inhalation of dust presented another source of risk. The luminosity of the material enabled its deposition as dust on chairs, tables, clothes, and even on the skins of the workers to be easily demonstrated. The reporters, although not considering their investigation absolutely conclusive, state their opinion that the necrosis is due to the radium paint. Blood examinations demonstrated an over-exposure to radium. Radium is deposited in bone, and literature presents cases of jaw necrosis among those who have received radium treatment for mouth cancers. This paper is clearly of interest to those using radium for remedial purposes. —— September: A method for sampling dust in alveolar air is reported by R. M. Thomson, who shows that such dust can be sampled directly by using Owen's jet dust counter, Kotze's konimeter, or Hill's dust counter, in conjunction with Haldane's alveolar air sampler. Analyses of exhaled air justify the assumption that samples of true alveolar dust are obtained by this method. A description of experiments in sampling alveolar dust is given, illustrated by photomicrographs. The method possesses a broad field of usefulness in studying the actual particles reaching the lungs of persons engaged in dusty trades, and it is apparently adaptable for use in analysing problems of bacterial inhalation in infected atmospheres.—A long and important article appears by M. Oppenheim on the statistics, definition, and clinical aspects of occupational dermatitis. This capable summary, based on Prof. Oppenheim's work over many years at Vienna, cannot fail to be of great interest to industrial physicians. It is, however, a summary, and its contents cannot be shortly exposed.

Reports and Analytical Records.

(1) "TABLOID" DIGITALIS LEAF (1 gr.); (2) "TABLOID" IODICIN (0·03 g.).

(Burroughs Wellcome and Co., Snow Hill Buildings, London, E.C. 1.)

(1) The administration of dried digitalis leaves in cases of organic cardiac disease is credited with physiological results of a uniform character. But there has been uncertainty as to the glucosidal content of the leaves which varies with the kind of seed, the method of collection and drying, and, of course, with the accurate physiological control of the finished drug. A welcome will therefore be extended to a 1 gr. product of digitalis leaf under the "Tabloid" brand. The cultivation of the digitalis has taken place at the "Wellcome" Materia Medica Farm at Dartford, where pains have been taken that the seed should be of the correct variety, and that the leaves are gathered and dried in the correct manner. Finally, the drug has been subjected to physiological control by the laboratories of the firm. The tabloids are issued in bottles of 25 and 100.

(2) "Tabloid" Iodicin (0·03 g.) (with chocolate base) provides a means for the prolonged administration of iodine to children. It is palatable and odourless, the chocolate base being designed to make the product acceptable to young patients. Its medicinal constituent, Iodicin, a calcium salt of iodoricinoleic acid, contains a high percentage of iodine in organic combination. One "Tabloid" Iodicin, 0·03 g., secures the administration of 0·01 g. (approximately $\frac{1}{6}$ gr.) of iodine. Iodicin is unaffected by the gastric juice and is absorbed only after passing into the duodenum. It is particularly suitable for prolonged administration as it does not cause digestive disturbance or iodism. It is issued in bottles of 25 and 100. The suggested prophylactic dose is one "Tabloid" product weekly, the curative dose from two to three products weekly up to one daily for 30 days. The drug meets the need arising out of the well-known Austrian and Swiss experiences in respect of goitre, which have been confirmed both in the United States and New Zealand.

(1) AGAROL BRAND COMPOUND (WARNER); (2) IDOSAL.

(Francis Newbery and Son, Ltd., 31-33, Banner-street, London, E.C. 1.)

(1) Agarol Brand Compound is a preparation of modified mineral oil with phenolphthalein and agar-agar. It is a homogeneous emulsion free from alkalies and sugar, and evidence is forthcoming that it acts as the named constituents suggest that it should. Thus it is a lubricant mixing with waste matter, rendering it soft and adding to its bulk, a normal bowel activity being in this way aided. The preparation is manufactured by Messrs. William R. Warner and Co. in New York.

(2) Idosal is a combination of the iodide and chloride of sodium, carbonate of magnesia, and phosphate of calcium, and has been recommended by medical men as a useful method of administering iodine in an assimilable form. Its description as a "supertonic table salt" is correct, but a warning is properly added upon the bottle that it should only be used as an ordinary table salt in moderation. The active ingredient is a prophylactic against goitre and useful in hypothyroidism, and having a definite iodine content can be recommended for therapeutic use. We noticed recently another preparation with similar claims to value in the treatment of goitre, and refer readers to an annotation which appeared in The Lancet of Sept. 19th, p. 615. The successful results obtained in different parts of the world in the treatment of endemic goitre by means of iodine are there recorded, though the ætiology of the disease has not been made as clear as the treatment.

(1) DOUBLE CREAM SOYA MILK AND YEAST; (2) SOYA MILK (SYNTHETIC MILK IN POWDER FORM) DOUBLE CREAM (UNSWEETENED).

(The Garden City Pure Food Co., Ltd., Letchworth, Herts.)

(1) *Double Cream Soya Milk and Yeast.*—This yellowish brown powder mixes with water in all proportions. It has a slightly saline and distinctly "meaty" flavour. On analysis the preparation was found to have the following composition:—

Moisture	2·00	per cent.
Ash	8·38	,,
Fat	56·70	,,
Protein	16·80	,,
Nitrogen-free extract	16·12	,,
Calorie value per lb.	2858	

Starch, cane-sugar, and reducing sugars were absent.

This material contains an unusually large percentage of fat and this, in conjunction with the protein, accounts for the high caloric value. The entire absence of starch and sugars, the ready miscibility with water (when a whisk is used), the high fat content, and the "meaty" flavour go to show that in this product the makers have furnished a valuable and highly nutritious addition to the limited dietary suitable for the use of diabetic patients.

(2) *Soya Milk (Synthetic Milk in Powder Form) Double Cream (Unsweetened).*—This is a yellowish powder, which, when mixed with water, produces a fluid very closely resembling a rich milk in appearance and flavour. When analysed the following figures were obtained:—

Water	2·24	per cent.
Ash	6·06	,,
Fat	66·00	,,
Protein	12·25	,,
Nitrogen free extract	13·45	,,
Calorie value per lb.	3139	

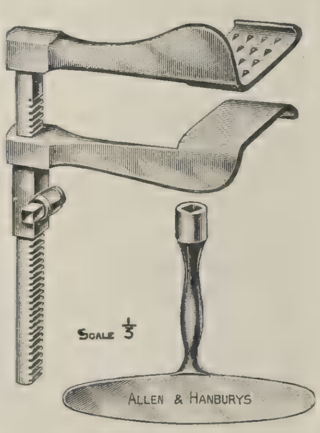
Starch, cane-sugar, and reducing sugars were absent.

For the purposes of comparison it may be noted that ordinary dried milk contains 25–27 per cent. of fat. The claim of the manufacturers that this milk may be valuable to persons suffering from diabetes is substantiated by the analytical data.

New Inventions.

A MODIFIED TUFFIER'S THORACOTOMY RETRACTOR.

After using Tuffier's thoracotomy retractor for several lung cases, I found the instrument was often unsatisfactory. The retraction obtainable by this instrument is usually inadequate owing to the difficulty in opening the blades by means of the thumb screw, attempts to do this often resulting in torn gloves. De Quervain's retractor, although mechanically efficient—retraction being controlled by means of a ratchet or cross handle—I find too unwieldy for general use. I have therefore had made a modification of Tuffier's retractor fitted with a powerful ratchet screw, which is operated by a removable T-shaped key (see illustration). This instrument has the advantage of being small and yet sufficiently powerful to give good retraction. Furthermore, the key can be removed and does not hamper the operator. Messrs. Allen and Hanburys, of Wigmore-street, are the makers.



Cecil P. G. Wakeley, F.R.C.S. Eng.

THE LANCET.

LONDON: SATURDAY, OCTOBER 24, 1925.

NON-UNION IN FRACTURES.

THE factors influencing the normal growth of bone are as yet imperfectly known; still less reliable knowledge have we of processes essential for the union of the fracture of an adult bone. That general metabolic derangement has a potent influence, the existence of bone changes in acromegaly and other diseases shows. It is therefore not surprising that unfavourable conditions of general health have always been held to cause delay in the healing of fractures. But in numerous cases of hindered union this factor can be definitely excluded. The cause seems to be a local one.

A fortnight ago we published a lecture by Prof. E. W. HEY GROVES, who reviewed such causes, voiced his own opinions, and gave advice as to treatment. He believes that one important cause of delayed union is unrestricted mobility, and he makes a very important distinction between two forms of non-union. In the one the unifying process seems simply in abeyance; the bone-ends, in X ray plates and if cut down upon, appear just to have remained unaltered from the time of the accident, whilst in the other there has been much activity of the bone-ends which have become sclerosed and eburnated, give a darker shadow with X rays, and are joined by dense fibrous tissue. The first variety will often yield to non-operative measures, whilst the second calls for them. Prof. GROVES insists that proper fixation is essential for union to take place. On this point Mr. J. W. DOWDEN joins issue with him in a letter appearing elsewhere in this issue. In an experience of 25 years he has but once met a fracture which would not unite, and that was of the clavicle, a result he attributes to having adopted the principle of mobility in the treatment of fractures. It does not seem likely that union would be favoured by free movements of the bone-ends on one another, a movement which would break down the adhesions between the opposing layers of granulation tissue. A laparotomy wound would certainly not heal if constantly dragged open. The granulation tissue bond must quite obviously remain intact for union to take place. This does not prohibit movements of surrounding muscles and neighbouring joints, and even a non-destructive bending of the granulation tissue junction at the site of fracture. Such movements improve the local circulation, empty the clogged lymphatics, and generally promote the healing process. Limited movements have proved their worth in the treatment of fractures. There is probably no real conflict of opinion on the subject of mobility, for the one surgeon advocates fixation of the fragments with movement of neighbouring joints whilst the other in recommending mobilisation treatment insists that movements should be active in character and painless. A patient with a fracture cannot very well be induced to move his limb enough to cause actual disturbance of the relation of the bone fragments to each other, for this provokes great pain and by reflex muscle spasm limits the causative effort.

In spite of careful treatment surgeons do meet with cases of non-union, and Prof. GROVES's classification into two types is of great practical importance. In the form in which cell activity fails, measures which further local nutrition should be instituted, a fact which suggests that such non-union may depend upon injury to the nutrient vessels occurring as part of the original accident. The slow repair after plating operations can certainly be attributed to extensive stripping of the periosteum which sometimes is unavoidable. When firm fibrous union with eburnated bone-ends occurs, an operation which removes the sclerosed tissues and opens up new paths for the osteoclasts becomes necessary. This points to some barrier to the growth of osteoblasts across the interval between the fragments being present from the first, since bone formation in the actual bone-ends is stimulated. The obstruction can conceivably be intucked periosteum, which as MACEWEN showed opposes great resistance to the through passage of bone-cells and possesses, in fact, bone-absorptive, as well as bone-forming properties. Nothing but an open operation will remove such an obstruction and allow the normal healing process to proceed. In the treatment of fractures both fixation and movement have their place. To apportion the right relative value to them, perhaps, would be to say that fixation of the bone-ends is an essential, whilst movement of the surrounding soft parts is desirable.

◆

THE MELANOMATA.

THE suggestive fact emerges again and again that the advances of morbid anatomy are often incompatible with the most sacred dogmata of orthodox biology. Thus, the "law" of the "specificity of the germinal layers" decrees that, once these layers are formed in the embryo, they proceed in their differentiation in certain directions only and give rise only to certain kinds of tissue for which they are "predestined" by this law. When, for instance, the formation of mesenchyme by budding from the primary germinal layers, the cells of which are of an epithelial habit, ceases, it ceases for ever. From now onward the cells of the ecto- meso-, and endo-derm remain epithelial. We may well ask: Why should a process that takes place upon an extensive scale during the early stages of development necessarily terminate at the precise moment at which it ceases to be observed by embryologists? May it not be that the capacity is now merely latent normally but subject to revival by the action of a pathological change? It might be well for biologists, before they tell pathologists that their education has been neglected when they describe phenomena that are contrary to "biological laws," to ask themselves if these "laws" do not, perchance, require revision in the light of pathological knowledge. There have been heterodox biologists—to mention only MAURER, SCHUBERG, and more especially RETTERER, who claim that mesenchyme formation continues throughout life. It is to be feared that their writings are not much read. RETTERER insists that practically the whole of the cutis is derived from the epidermis by post-embryonic budding of its cells.

Pathologists can, of course, form no authoritative opinion of the merits or demerits of writings which are concerned with the phenomena of normal growth, but there are many instances of abnormal growth of an analogous nature which are within the province of pathology. The whole of the October issue of the *Edinburgh Medical Journal* is given up to a monograph [1] by Dr. J. W. DAWSON upon the melanomata, which is heretical and open to the severest disapprobation of orthodox biologists since he is unafraid to tell us what he has learned from the study of his material. He has approached his subject with an unbiased mind and, after careful consideration of the contending views, has been driven to the conclusion that the melanomata are epithelial tumours, the result of post-embryonic, pathological attempts at the conversion of epithelium into mesenchyme, attempts that are often crowned with success. The idea is not new. It was propounded nearly 40 years ago by KROMAYER, UNNA, and others, and has since then gained an ever-increasing number of adherents. Dr. DAWSON'S material is rich and well digested. His illustrations are admirable, and unlike so many morbid anatomists he realises that they form the surest proof of his arguments. His conclusions fall into two groups. He shows that the pigment melanin is produced solely by the epithelial cells of the ectoderm—i.e., the epidermis and its appendages and the central nervous system. True "melanoblasts" are epithelial cells which may, however, enter the deep tissues. They are distinct from the mesenchymal "chromatophores" which ingest the pigment by phagocytic action but do not produce it. He traces the formation of the "nævus" cells from the epithelium in cutaneous moles and the melanotic tumours which arise in them. With the help of beautiful drawings he shows the extreme polymorphism that the cells of these tumours assume and that the melano-carcinomata, -sarcomata, -fibro-sarcomata, &c., are but different forms of the same tumour. He concludes that even the most "sarcomatous" melanomata are epithelial tumours and extends this conclusion to the ocular melanomata. It is to be regretted, for the sake of completeness, that he does not deal more fully with the rare recorded instances of melanomata of other parts of the body. Dr. DAWSON does not go so far as KROMAYER and admit a complete "desmoplasia" (or assumption of all the characters of connective tissue) of epithelial cells. He is perhaps wise not to do so. His paper is a valuable contribution to the question of the specificity of the germinal layers, which will have to be considered not only by pathologists but by general biologists.

A CONQUEROR OF INSECT PESTS.

Prof. MAXWELL LEFROY, whose obituary notice appears on another page, was perhaps the foremost economic entomologist in the British Empire. In the course of his career he had three really spectacular successes. The first was when he went to the West Indies. The sugar-cane, on which the prosperity of the islands depended, was being destroyed by a beetle which bored into the stems. LEFROY discovered that the eggs of this insect were laid on the backs of the leaves; he described the appearance of the egg-clusters, and small native boys were employed to scrape them off the leaves and the sugar-cane crop was saved. When he arrived in India the corn crops in certain districts were being devastated by a plague of locusts. The seriousness of the situation may be judged from the fact that the crop reaped was only 25 per cent. of the normal yield, and in India, where the peasant proprietors live close to the margin of subsistence, there was imminent danger of famine. LEFROY discovered that the locusts kept flying about the same locality until the rains came and softened the ground; they then descended to the ground and laid their eggs in holes bored in the earth. Once the period of oviposition was determined, it was easy to calculate when the wingless young (*nymphs*) would hatch out, and LEFROY constructed what may be termed shrimping-nets out of light bamboo and sent the native boys with them through the growing corn, with the result that the young locusts were captured by the sackful and the next year's crop was normal. Lastly, when he was sent to Australia in the latter part of the war he had also a very serious situation to deal with. The Imperial Government had purchased large amounts of Australian wheat which was stored in Australia where it was being rapidly destroyed by weevils. LEFROY discovered that the wheat was contained in sacks which were piled on the ground covered with insufficient roofing and inadequately protected against rain and damp. The lowest bags burst and the grain exuded and thus easy access was afforded to the weevils. LEFROY found that the grain weevil was an insect which had lost the use of its wings and that it always began its attacks by entering grain lying on the ground, so he directed that the grain should be housed in sheds provided with an adequate flooring raised two or three feet above the ground and that the soil beneath them should be treated with disinfectants such as naphthalene. These measures were entirely successful in stemming the weevil plague. LEFROY always insisted on the importance of studying insects in the open under natural conditions. Quite early in his career he laid down the thesis that to attack an insect pest successfully its whole life-history must be studied; then the weak links in its chain of developmental stages would be discovered where the attack could be successfully pressed home. Whilst he recognised the importance of a knowledge of their structure, which is as indispensable a pre-requisite as the study of grammar in learning a language, he maintained that all further knowledge should be gathered in the field. "One must live with insects," he said, "in order to know them."

VACCINIA AND VARIOLA VIRUSES.

THE ultramicroscopic viruses are notoriously difficult to study, for obstacles, in some cases seemingly insurmountable, are encountered by whatever avenue the territory of these smallest of living creatures is approached. Too small to be directly visible with the microscope, difficult to cultivate, and, even if cultivable, without distinctive reactions, we have been left only with the crude test of demonstrating their presence by inoculation of a bacteria-free filtrate into living animals. Filtration and inoculation experiments, depending as they do on such variable factors as the construction of the filter and susceptibility of the animal, have not hitherto encouraged accurate quantitative work. Perhaps some entirely new method of approach must be discovered before these ultramicroscopic viruses can be scientifically classified. In this connexion it is instructive to notice that Dr. Mervyn Gordon, in his studies on the viruses of vaccinia and variola (summarised in our last issue), has departed from the conventional technique of bacteriological examination, for we read practically nothing in his report of attempts to see these viruses with the microscope, or to stain them, or even to cultivate them in the customary fashion. He has relied entirely on experimental work on animals and is to be congratulated on having succeeded in introducing more accurate quantitative methods of analysis. He found the shaved skin of the rabbit a delicate indicator for vaccinia virus and devised methods for measuring the minimal vaccinial dose, and has made a careful study of the properties of antivaccinial serum by quantitative means. The most sensitive test for the presence of vaccinia virus is undoubtedly the cutaneous test of virulence, but the complement-fixation and agglutination tests, though their range is shorter, are not lacking in specificity, and, since they provide an independent measure, they form a welcome addition to our armamentarium. The special feature of Dr. Gordon's work is the successful employment of serological methods, which has been made possible by employing homologous (rabbit) pulp as a virus, and the proof that complement fixation and agglutination occur with vaccinia virus in much the same way as with pathogenic bacteria brings vaccinia into line with the latter group. The experiment in which an immunised serum produced a definite immunity are also of interest.

Some of the experiments which Dr. Gordon reports in the permeability of various surfaces of the rabbit to the virus of vaccinia raise the question whether the main natural method of spread of this bovine disease may not be in part by the respiratory tract rather than by fortuitous cutaneous inoculation as hitherto supposed. He found the most certain way of introducing the vaccinial virus to be by scarification of the skin, but in the absence of mechanical injury the most susceptible and permeable of the surfaces of the rabbit seems to be the nasal mucous membrane. When vaccinia virus gains access to the nasal mucosa, after an incubation period of six to eight days, a condition of acute nasal catarrh develops, accompanied by a muco-purulent nasal discharge which at the onset contains the virus of vaccinia in abundance. Animals thus infected became immune to vaccinia. Confirmatory evidence of the capacity of the nasal mucosa to absorb antigen was furnished by control observations in which the application of killed *B. coli* to the mucous membrane of the nose was followed by the appearance of specific antibodies to that micro-organism in the blood. He observes that the limits of this physiological property of the nasal mucosa and the degree to which it can be exploited for prophylactic purposes have still to be determined. The acute attack of nasal catarrh which follows after an incubation period when the vaccinial virus has gained access to the nasal mucous membrane links up the disease which we call vaccinia to the group of influenza and the common cold. It is important that we should obtain further information on the natural distribution and mode of spread of vaccinia virus in the animal kingdom. Thanks to the accurate analysis which Dr. Gordon has made we now possess a triple index—namely, the cutaneous virulence test, the agglutination, and complement-fixation tests, wherewith to identify the presence of vaccinia virus and to estimate its abundance.

A point of great practical importance demands a word of emphasis. Dr. Gordon found when studying seven different kinds of calf lymph in use in this country for purposes of vaccination that these varied very greatly in their potency. Some were active at a dilution of 1 in 100,000 and others only at a dilution of 1 in 100 or even 1 in 10. Since calf lymph is known to deteriorate on keeping it would have been interesting to know something more of the history, particularly the age, of the samples examined. No information on this point is given in the report, but as the facts are presented they seem to suggest that a very significant and inexcusable variation exists in commercial samples of calf lymph. Obviously this is a question which requires official attention. A further feature of Dr. Gordon's work which has practical implications is his research on the comparative value against vaccinia of disinfectants. The striking powers of potassium permanganate which he reveals should encourage its use in small-pox, which has hitherto been largely empirical.

Annotations.

"Ne quid nimis."

THE CATARRHAL CHILD.

The importance of catarrhal conditions in childhood in laying the foundations of future disease has received a greatly increased measure of recognition during the present year. This recognition is evidenced by the appearance of several contributions to medical literature which show not only that pædiatrists of high standing in medical practice and in the public services have given their serious attention to the subject, but that their observations have led them to differ in important respects from many of the earlier accounts of catarrhal states. A notable instance of this difference is to be found in the age which is regarded as typical for the onset of catarrh. The "catarrhal child," as hitherto depicted, is usually in the second year of life, or older, and presents features which are either typical or suggestive of rickets; by many writers the catarrhal symptoms have been regarded as essential manifestations of rickets, the causative factors being, at any rate, nutritional and environmental. The article by Dr. R. C. Clarke, which appears in our present issue, introduces some striking modifications of this conception of the ætiology and incidence of catarrh. According to his account, respiratory catarrh is extremely common in the first few weeks of life, being present in as many as 50 per cent. of the infants which he examined. He has frequently noted the presence of Harrison's sulcus in young infants, and regards it as evidence, not of rickets, but of nasal obstruction consequent upon catarrh; he bases the diagnosis of respiratory catarrh on this sign in conjunction with snuffles and bronchial râles. In early infancy nasal catarrh is almost always accompanied by bronchial catarrh, whereas in late infancy the majority escape this complication, hence the prime importance of protecting the infant from infection during the first three or four months. Dr. H. K. Waller, in a memorandum on the catarrhal child, which appeared in the recent report of Sir George Newman to the Minister of Health, gives a description of this type of case, which is in many respects in close agreement with the views expressed by Dr. Clarke. The prevalence of catarrh in the first weeks of life is emphasised, as are also the interference with efficient sucking, and hence with nutrition, the development of "tonsils and adenoids," and the increased susceptibility to febrile attacks and to infection with pyogenic organisms. Both Dr. Clarke and Dr. Waller lay stress on the necessity of protecting the infant from catarrhal organisms, and recommend as the most useful measure for this purpose the use of a mask or folded handkerchief by the mother or nurse who is attending to the child. On the more speculative problem of ætiology the agreement between the two articles is less complete. The traditional association between rickets and catarrh must necessarily be called in question by those who regard the latter as an ailment of early infancy. Dr. Clarke does not discuss this point; Dr. Waller meets it with a suggestion which inverts the hitherto established view of the causal sequence. "The rachitic child's tendency to febrile reactions has been frequently described. It is possible that the catarrhal diathesis has been overlooked as a predisposing factor in producing rickets." A further question inevitably arises if the typical age-incidence of a morbid state is found in the first weeks of life: Does heredity play a part in the ætiology: Dr. Clarke answers this decidedly in the negative: Dr. Waller gives cautious expression to the idea that a hereditary element is likely. Should both Dr. Waller's suggestions receive further elaboration, he may provide one more complication to the vexed problem of the ætiology of rickets.

THE CARE OF THE CONVALESCENT.

When a patient has "turned the corner" of a grave illness and it is safe to relax the vigilant care he has hitherto demanded, the doctor is liable to lose interest to some extent in the further progress of the case. It is a very natural reaction from the strain of his heavy responsibilities; when recovery is practically assured he can minimise the output of his mental energy and with a cheery "How are we to-day?" can chat of irrelevant matters with a vague idea of "cheering the patient up." Yet to the patient himself the period of convalescence is, perhaps, the most trying part of the illness. In the acute stage he lies passive, concentrated on the one supreme effort of battling for life, and released from all other responsibilities by the assiduous care of doctor, nurse, and friends. As life comes back gradually from this relatively simple form to the highly complex thing that modern civilisation has made it, his enfeebled powers are apt to groan under the burden they have once more to pick up and carry. The "fractiousness of convalescence" is so unimportant compared to the life-and-death issues we have to control as best we can that doctors and nurses are too prone to dismiss it with a patronising smile and forget that the patient is not fractious from love of evil or original sin, any more, indeed, than is the child; both are struggling with an adjustment to life that is slightly overtaxing their powers of adaptation. The convalescent period is well worth the thoughtful attention of the practitioner. The Public Health Committee of the New York Academy of Medicine recently appointed a sub-committee to consider the problem of convalescent care. In presenting their report[1] the Committee say that "it is remarkable that more has not been accomplished in the way of making provision for the care of convalescent patients. Homes have been established on no coördinated plan . . . . without much realisation of the various types of convalescence, and the needs of adult convalescents have received scant attention. No doubt one of the main reasons is that hitherto not enough study has been made of the subject." They begin by drawing a clear line of distinction between patients progressing towards recovery from some acute illness and those with persistent symptoms of functional disturbance but with slight or no evidence of organic disease. The first group they classify, according to the type of disease, as cardiovascular, dietetic, respiratory, and miscellaneous, and for each a different régime of convalescence should be provided. Those for whom special dietetic supervision will be required must further be subdivided according to whether they are diabetic, nephritic, or alimentary. But the medical classification, although it may be adequate enough for acute stages of illness, is only a small part of the total to be considered in catering for the convalescent. Age, sex, social status, religion, financial resources must all be allowed for, as well as that ever-present problem of the slum-worker: the convalescent mother with a toddling family that cannot be left at home alone. Last, but by no means least, is the individual temperament. One case will fret himself ill with boredom if sent to a country house five miles from the station; another will lose half the benefit of his convalescence if it is spent hectically at a popular seaside resort.

The American report deals chiefly with the convalescent home, and is of the opinion that the ideal home is a system of cottage units, arranged in single rooms, and three- or four-bed wards situated a little distance outside the urban area it serves. The patients should be selected according to the classification suggested, and should be subjected to a daily schedule of living, prescribing their hours of rising, rest, and retiring, physical exercise, recreation, social diversions, and diet. The cardiac group must have a home of two floors only in a low-lying district, while the respiratory group need more than their share of fresh air. The aim of the home should be educational as well as restorative, so that the patients learn habits of hygiene which they can carry back to their own homes. The Committee recommend the appointment of a resident medical officer to every convalescent home—a far-reaching reform if a possible one. While the ideal—if somewhat bureaucratic—conditions laid down by the Committee are not likely to be attained in this haphazard world, they will have done a real service to the profession and the community if they stimulate the average practitioner to giving more real thought and care to the planning of his wealthier patient's convalescence or the choice of home for the poorer.

CANCER-LIKE CHANGES IN TISSUE CULTURES.

In a recent paper [1] Dr. R. J. Ludford described nuclear changes occurring in the fibroblasts from the kidney of rats cultured in vitro. Fixed preparations show a partial extrusion of nucleolar matter into the cytoplasm where it is surrounded by a vacuole, and eventually disintegrates. This process is accompanied occasionally by a similar passage of a portion of the nuclear contents into the cytoplasm by a process of budding off. The extruded nuclear contents may persist for a time as a secondary nucleus and then break down. In fresh unstained cells kept in a warm chamber amœboid movements of the nucleolus could be observed, and also a movement of the nucleolus towards and away from the nuclear membrane with occasional indications of a discharge of nucleolar material into the cytoplasm. Prolonged observations in fresh cells were rendered difficult by the fact that at body temperature the nucleolus and nuclear membrane are more difficult to distinguish than when the preparation is allowed to cool to room temperature. Such nuclear extrusions occur also in normal cells in the living animal, though infrequently, but they are of common occurrence in cancer cells, where in the past they have been mistaken for cancer parasites. Dr. Ludford does not attempt to interpret these changes except as giving evidence of an interaction of nucleus and cytoplasm. But it seems reasonable to suggest that their frequent occurrence in cancer and in normal cells cultured in vitro may be associated with abnormal conditions of growth and nutrition.

Writing on the same subject,[2] Prof. A. Maximow records and figures even more pronounced changes occurring in the mammary gland cells of the rabbit cultured in vitro under special conditions. The special conditions are the addition of bone-marrow extract, instead of embryo extract. The addition of bone-marrow extract elicits not only a rapid growth especially of the cells lining the ducts, but also hypertrophy of the cells, changes in their form, formation of cell nests, and even an infiltration of the connective tissue. It is noteworthy that these changes are exhibited almost entirely by cells derived from the epithelium lining the ducts. As a result, many of these cultures present appearances which are morphologically indistinguishable from those of a carcinoma. Indeed, Maximow speaks of these appearances as "carcinomatous changes." He realises that definite proof of such a change having actually occurred in these cells can only be brought by reimplanting these cultured cells into a living animal. If these cells have really undergone a carcinomatous change they should, on reimplantation, continue to grow in vivo. But while a positive result would prove his contention, a negative would, according to Maximow, not necessarily disprove it, because even spontaneous carcinomata do not always give positive results on transplantation.

The resemblance of Prof. Maximow's tissue cultures to carcinoma is so suggestive that his contention deserves to be submitted to exhaustive experimental tests. At the same time it is well to bear in mind that this resemblance is merely morphological and may be no more than the manifestation of growth under abnormal conditions. It may, in fact, bear the same relation to cancer as the noise and clatter of a passing train has to the electricity that moves it.

VITAL STATISTICS OF SCOTLAND IN 1924.

THE seventieth annual report of the Registrar-General for Scotland contains many tables of interest to the student of vital movements. But he can hardly fail to regret that this report, like other Scottish statistical reports, is not tabulated and classified on identical lines with the corresponding English reports, and that no comparative figures for the two countries and some other countries are given. The value of both the English and the Scottish reports is materially lessened thereby. The course of the Scottish birth-rate is downward, like that for other countries, but its cause has differed in detail from that of England. Until 1894 it was always over 30 per 1000, but is now only 21·9. As is well-known, the illegitimate birth-rate is high in Scotland. In 1924 it varied from 9·3 in the larger burghs per 1000 unmarried women of child-bearing ages to 13·3 in the country districts. It was as high as 24·8 in Moray, and as low as 4·7 in Shetland. This high rate is not a correct index of sexual morality, and must be corrected inter alia by reference to the marriage laws of Scotland. The average age at marriage is of interest in this connexion, having been 29·35 years for all bachelors and 26·56 for all brides. This shows a gradually increasing postponement of marriage.

From the public health point of view, the review of the Scottish vital statistics presents features of much interest. The rate of infant mortality was 97·7 per 1000 births, a low rate compared with past experience, but high, relatively, to that of England. It varied in the larger burghs from 132·9 in Paisley and 118·5 in Glasgow to 90·7 in Edinburgh and 90·6 in Perth. There is no full index to the report, but no attempt appears to be made to analyse for the whole of Scotland or for its chief towns the distribution of infant mortality in the months of the first year of life, information which is an indispensable preliminary to any attempt to ascertain at what ages infant mortality is most excessive, at what ages it is higher in some burghs than in others, and to what causes these local excesses are due. Such information as is here indicated, but expanded, is an urgent necessity for public health purposes. It is necessary that it should be done comparatively for different areas in Scotland; and the rates thus published would be invaluable as guides to medical officers of health in pressing forward accurately-directed public health work. It is satisfactory to note that for the first time in its statistical history no deaths occurred last year from typhus fever. The tuberculosis death-rate was 116 per 100,000 of population, a lower rate than in any preceding year. This is higher than that of England, and the variations in different parts of Scotland are so remarkably great as to bespeak the need for special public health investigation. Thus, in Shetland the tuberculosis death-rate was 247 (per 100,000). The population being small, this means 59 deaths; but evidently this is a case in which intensive effort at public health administration with better housing might be expected to effect rapid improvement. The next highest tuberculosis death-rates were 158 in Sutherland, 156 in Ross and Cromarty, the counties with a large population having the lowest rate being Fife (87 per 100,000) and Ayr (84 per 100,000). In Lanarkshire, which comprises nearly one-third of the population of Scotland, the rate was 132. Only a short paragraph is devoted to the important public health problem of puerperal mortality. For the whole of Scotland this reached the high figure of 5·8 per 1000 births, varying in the larger burghs from 12·2 in Coatbridge and 11·7 in Perth to 5·8 in Glasgow, 4·7 in Aberdeen, and 3·9 in Dundee.

Further tables bearing on the main problems of public health, including those indicated in the preceding paragraphs, would add greatly to the value of the Scottish statistical report, and it may not improperly be suggested that a chief value of the tabulation of registered deaths according to age and cause of death lies in the extent to which they make manifest areas of excessive mortality in one or other respect, and enable medical officers of health and sanitary authorities to direct their efforts to improve the national health where they are most needed and where their effect will be greatest.

RADIOTHERAPY AT LEEDS.

THE General Infirmary at Leeds is to be congratulated on the recent addition of a new radiotherapeutic department, the creation of which has been made possible by the generosity of two donors, Mr. J. B. Sykes, of Horbury, who has presented the building, and Miss Walker, of Chapeltown, Leeds, who has met the cost of the artificial sunlight apparatus. Through this gift Leeds now possesses one of the largest and best departments of its kind in Britain. The new building measures over 100 ft. by 45 ft., and contains 11 treatment rooms as well as instrument rooms, waiting rooms, staff rooms, dressing rooms, and workshop. The building is very airy and well lighted, and a broad corridor down the centre provides access to the various rooms. Five of the treatment rooms are devoted to deep X ray therapy, and each cubicle is equipped with apparatus capable of generating 200,000 volts and upwards. Provision is made for the housing of the apparatus in a large instrument room at the back of the cubicles. Special care has been taken to provide for the adequate protection of the staff by heavy lead linings in all the cubicles, and the controls are placed in a special room outside within easy reach of the operator. The cubicles are lofty and are lighted from above, while central heating has been adopted throughout the building. The "artificial sunlight" department consists of six treatment rooms; the two largest, measuring 20 ft. square, are for men and women respectively. Dressing rooms are attached to each, and an observation room is provided so as to control both treatment rooms. Each room is equipped with two "Mountain Sun" mercury-vapour lamps, and two arc lamps together with special radiant heat lamps. A separate room for the treatment of cases unable to sit or stand is equipped with lamps which can be used while the patient reclines on a couch. Another room is reserved for children, and similar equipment of arc and mercury-vapour lamps has been provided here. A special room for treatment by the Kromayer lamps is placed at the end of the long corridor, and one of the largest rooms has been set apart for Finsen light treatment of lupus and similar diseases. At present upwards of 100 cases a day have been receiving "artificial sunlight" treatment, but the new department will extend the scope of daily treatment to over three times that number. With this equipment we may confidently expect that Leeds will achieve results not only of immediate benefit to local patients, but of value to the progress of this branch of medical science.

PIONEERS IN TROPICAL MEDICINE.

WE are apt to regard tropical medicine as a child of recent infancy, but several years before the battle of Waterloo it was a well-grown stripling, although it did not come into its full inheritance until the present century. Pioneers in Tropical Medicine was the subject of Dr. Andrew Balfour's presidential address to the Royal Society of Tropical Medicine and Hygiene held at 11, Chandos-street, London, on Oct. 15th, when, with the aid of beautifully prepared portraits on the epidiascope, he gave cameo biographies of the men who throughout the nineteenth century—and before—had toiled to raise the symbol of Æsculapius along with the British flag in all corners of the world. The list of British pioneers, and in this field Scotsmen are well to the fore, is a long one; in the course of an interesting hour Dr. Balfour could do no more than briefly touch on the more outstanding figures of that company. The stimulus to the study of tropical diseases was first felt in the fighting services in their campaigns overseas in the warring years of the late eighteenth century, and it was Sir John Pringle (1707–83), "a pursy and peppery gentleman," who founded military hygiene, groping his way in the dark without the aid of such useful things as statistics or precedents. He published a book in 1775 on Observations on Diseases in the Army, and was subsequently elected President of the Royal Society. From his works we know how common in those days was helminthiasis, and he specifically recommends bleeding in the crises of malaria, "which," Dr. Balfour said, "was not at all a bad idea"; but he is best remembered as a hygienist who made a careful study of the rationing and the diet of the soldiers. His parallel in the senior Service was James Lind (1767–94), perhaps a greater man even than Pringle. He served in the tropics and there gained a first-hand knowledge of local diseases. He was a man singularly modern in his ideas, an earnest worker, and a clear thinker. With him two other names are associated, Sir Gilbert Blane, who introduced lemon juice into the Navy as an antiscorbutic, and Surgeon (Thomas) Trotter. They were a wonderful trio, thrown together in the wars against France. Pringle was followed by Donald Monro (1729–1802), who wrote an amazingly modern essay on the preservation of the soldier's health in camps. Among many names worthy of record are those of Benjamin Rush, who first described dengue, and by his energetic efforts did much to quell the outbreak of yellow fever in Philadelphia in 1793, and Annesley, of Dublin, who recorded the experience of 30 years' service in the tropics. In the middle of the nineteenth century George Biddy showed that the spread of cholera was due to human intercourse; Edmund Parkes (1819–76) suggested the possibility of healthy carriers, and John Snow went a step further and reasoned out that the poison of cholera was contained in human excrement. Biddy also introduced humane treatment of the insane in India, and in 1886 he instigated the systematic inspection of Indian school-children. Among the Americans after Rush who have done pioneer work in tropical medicine comes Josiah Clark Nott, while Walter Reed and Surgeon-General Sir William Crawford Gorgas are familiar names. Women, too, have played their part in this great work, although not perhaps in a strictly medical or scientific field, and Dr. Balfour gave a brief history of the lives of Florence Nightingale, Mary Kingsley, of West Africa, and Mary Slessor, of Calabar. The spirit and achievements of Dr. David Livingstone was the vanguard of medical advance in the dark continent. Dr. Balfour drew shrewd conclusions from the portraits he showed on the screen as to the characters of the subjects, which made his lecture one of living and personal interest.

PEPYS AND SCIENCE.

THE Master of Christ's College, Cambridge, himself a writer of picturesque accuracy, is the very man to write with understanding and sympathy about that delightful seventeenth century Horace Walpole whom we know as Samuel Pepys, secretary to the Admiralty. In the current *Quarterly Review* Sir Arthur Shipley points out how science in Pepys's time was the "object of an insatiable curiosity, perhaps in a way childish," and how Pepys himself was insatiably curious. Nothing was too odd or too trivial for his notice and record. On March 14th, 1662, he met a German, Dr. Kuffler, who came "to discourse with us about his engine to blow up ships," a subject naturally interesting to a high official of the Admiralty. Although he only began to learn the first four rules of arithmetic in his thirtieth year, he was yet a great friend of Edward Cocker, who engraved a slide rule for him. On account of his defective vision he took much interest in optics and records how in company with Mr. Spong and "my twelve foot glass"—i.e., one with a focal length of 12 feet—"we did see Jupiter" and had "several fine discourses upon the globes this afternoon, particularly why the fixed stars do not rise and set at the same hour all the year long, which he could not demonstrate, nor I either." Let us hope that comprehension is wider nowadays. Pepys was elected to the Royal Society in 1665 and in 1684 became its President. It was during his term of office that Newton's immortal work, the "Principia," was accepted and published by the Society under Pepys's imprimatur. Many passages in the diary are quoted by Sir Arthur Shipley, which show how constantly Pepys attended meetings and demonstrations, several of which dealt with transfusion of blood. He also at "my Lord Crewe's" and other places met various learned persons who told him extraordinary stories about swallows hibernating, a belief which even Gilbert White held, and one of these, Mr. Templer—"an ingenious man and a person of honour he seems to be," says Pepys with unwonted caution—told a story of how serpents in Lancashire catch larks by crawling under a soaring lark and with wide open mouth eject their poison, whereupon the lark falls down into their jaws. Many similar startling episodes in natural history will be found in the pages of the Revd. Edward Topsell, who wrote a "History of Beasts and Serpents," to which Dr. Muffett contributed a section upon insects. Pepys relates a story from Muffett about Dr. Caius, and it is not unreasonable to suppose that he was acquainted with Topsell's book, the matter of which would certainly have interested him. So many facets did Pepys present to the world that, as Sir Arthur Shipley puts it, "he appears to have been almost globular."

RADIOGRAPHIC DIAGNOSIS OF SPINAL DISEASE.

IT seems that French radiologists of eminence have found difficulty in distinguishing between a malignant metastasis and a tuberculous condition such as Pott's disease. French descriptions of the differential diagnosis are brief and inadequate, one recent publication dismissing the matter with the statement: "The invaded bodies show abnormal transparency. The spongy tissue progressively disappears; the vertebral body crumbles; as a result there are deformities analogous to those of Pott's disease." A well-illustrated monograph[1] by Prof. J. A. Sicard and MM. J. Belot, Coste, and Gastaud makes good this defect. These investigators divide metastatic cancer into three main types—osteoporotic, osteoplastic, and para-cancerous changes. Under the first heading they discuss the differential diagnosis of Pott's disease and neoplastic metastases, pointing out that the latter are primarily and always osseous, and never cause any alteration in the intervertebral discs, even in an advanced stage. Generally the destruction results in a thinning of the vertebra until it becomes less than a fifth of its normal height. The disintegration of the vertebra is always more visible on the side than on the front, and is often the only radiological evidence. The compression of the body seems to compensate, from the point of view of transparence, for the structural alteration. Screening the spine may be the only means of diagnosing new growth of the prostate, so often symptomless at the primary focus. It is characterised particularly by an osteoplastic metatasis first described by Recklinghausen in 1891. At post mortem a great many of the bones are found thickened, eburnated, and abnormally hard. The remarkable diffuseness of the lesions is the most striking feature; starting from the primary focus in the prostate the process attacks first and most extensively the lumbar region and pelvis, but extends even up to the ribs and humeral heads. Naturally, the resulting anæmia is marked, and Assman diagnosed a prostatic growth on this anæmia combined with bilateral sciatica alone. A less exuberant osteoplastic form of metastasis is met with in mammary and pyloric cancers. The thyroid metastases, on the other hand, are exclusively of the decalcifying, destructive, "osteoclastic" type. The osteoplastic reaction may also take the form of "opaque vertebra," a condition reported by MM. Souques, Lafourcade, and Terris from a case of mammary scirrhus at the Salpêtrière. These opaque vertebræ are seen in cases where syphilis is present and may be the cause, but the authors prove conclusively from post-mortem cases that cancerous "opaque vertebræ" exist. Under the heading of "paracancerous lesions," the authors discuss whether a cancer can destroy bone from a distance without the actual presence of its cells, thus preparing the way for a metastasis. At present they do not feel justified in postulating more than paracancerous bony dystrophy. In a case of prostato-pelvic cancer under their care a radiological examination revealed a medullary-osseous fibrosis with hypercalcification throughout the whole skeleton, exactly similar to that associated with epitheliomatous infiltration in the lumbar region. H. Roger [2] has recorded a case of cancer of the breast showing a similar change in parts remote from any direct infiltration or metastasis. Primary tumours of the vertebral column are not common. Sarcoma tends to start on the outside and grow into a large tumour of the back without compression of the cord. Secondary neoplasms, according to Fraenkel, never give this large enveloping shadow, but the distinction is not quite so absolute as he implied. The radiological diagnosis of vertebral rheumatism, infectious arthritis, osteomalacia, traumata, and malformations are also discussed.

GERMAN MEDICAL CONGRESS.

THE Deutscher Aerzte-Vereinsbund held its annual meeting this year in Leipzig in association with the Leipziger Verband, the great medical union which is now called Hartmann-Bund in honour of its late founder; 267 delegates were present, representing medical societies and local branches with a total membership of 33,581. After the usual addresses of welcome the meeting discussed the suggested codification of medical etiquette. The proposal contained rules on professional secrecy, on advertising, and on the question of the qualification of specialists. The sale and the purchase of a medical practice is held to be unprofessional except in cases where the widow or the children of a deceased medical man offer his practice for sale. It is further unprofessional to criticise other medical men, to give medical advice, or to practise during a holiday stay in a health resort where other medical men are settled, and to give testimonials for "secret" medicines. The establishment of a joint practice is allowed only between specialists of the same branch or between general practitioners, but not between a specialist and a general practitioner. Canvassing is strictly forbidden and contracts allowed only under the rules of the Hartmann-Bund. Owing to the difficulties of the matter the codification was entrusted to a special committee for consideration. Another subject of discussion was the rôle of medical men with regard to the extensive physical culture activities which are now very popular among the younger generation of the German people. Special courses of instruction in the examination of amateur athletes have been instituted in several cities and universities. It was resolved that the medical advisers of sports societies must examine the members only as to their ability for the particular sport practised, but must strictly refrain from attending members in a general way. The forthcoming reform of the German criminal code, although it has not yet been brought before Parliament, was then discussed from a medical point of view. The principal items of medical interest are that a criminal shall be held responsible for his actions even when in a state of diminished consciousness caused by drunkenness, drunkenness being no longer regarded as an extenuating circumstance. Drunkards shall be subjected to special measures, such as compulsory detention in an asylum, prohibition to obtain intoxicating liquor, loss of civil and voting rights. Other items of interest deal with homosexuality which shall continue to be a criminal offence for men but not for women. Professional secrecy shall not be binding when it conflicts with the public interest as, for instance, in the case of infectious and venereal diseases. On the question of criminal abortion, which had already been discussed in the Bavarian branch of the Association (see THE LANCET, Sept. 19th, p. 620), this meeting came to the same conclusion as that branch. A communist delegate pleaded for absolute liberty in the matter of abortion as existed in Russia, because, he said, abortion should be regarded not from an ethical but from an economic standpoint. Finally the Congress discussed the question of quackery and unqualified practice and voted for its absolute suppression and for an alteration of the law to that end. Jointly with the Aerzte-Vereinsbund, the Hartmann-Bund discussed questions connected with club practice, the extension of the club system to the middle classes, and the systematic distribution of medical men throughout the country.

ATHLETICS AND ECONOMY.

THE review which we publish of Mr. Gilbert Bourne's book on oarsmanship recalls to mind part of Prof. A. V. Hill's address to the British Association on the Physiological Basis of Athletic Records.[1] Wasteful effort in muscular movements may be usefully demonstrated by the slow-motion cinematograph, and the economical use of energy is of no less interest when studied physiologically. According to the observations of A. V. Hill and H. Lupton the maximum efficiency of human muscular movement is obtained at speeds of about one maximal movement per second. In rowing, experience agrees that such a speed is about the optimum; in an eight-oar boat the recovery takes almost as long as the stroke, and 32 strokes per minute is generally regarded as the most efficient rate. By a muscular mechanism depending on the formation of lactic acid the body can get into debt for oxygen, and the amount to which this is possible varies with the individual; but when the account has been overdrawn to the extent of more than about 15 litres of oxygen (1 litre of oxygen consumed liberates enough energy to raise one ton about seven feet), the average athletic man becomes incapable of further effort. Thus, although it is permissible in a very short rowing race to work less efficiently by adopting a faster stroke, the work done will not be proportionately greater, and exhaustion will soon set in. When the body is working against an external resistance as in rowing there is an optimum speed, and if the effort is to be long continued it must be made at a speed not far from this optimum. In running, however, the work is absorbed by the viscous-elastic properties of the muscles or internal friction, and there is no optimum speed; the expense of the movement increases continually as the speed goes up. According to Prof. Hill a speed of 280 steps per minute requires 24 litres of oxygen per minute, whilst a speed of 240 steps per minute requires only 8 litres. Great effort is obviously not economical. It is said that to run a railway train at 50 miles an hour needs twice as much coal as to run it at 40, and accordingly the railway companies are prejudiced in favour of the latter speed. In the same way the average citizen in sedentary employment rightly refuses to develop his muscles and his powers to the pitch advocated and demonstrated by the late Mr. Eugen Sandow. Training may increase the ability to get into debt for oxygen and it certainly makes for accurate muscular movement, but whilst none can deny the value of exercise it is unnecessary to develop great athletic power in those whose station in life does not give a high value to strength or rapid movement. "The little more, and how much it is" is of great value in creating records, but the immediate or ultimate price is often unduly high. Writing in The Lancet (1914, i., 950), Sir Thomas Oliver mentioned the premature ageing of professional footballers, drew attention to the dangers of sudden overstrain, and continued: "One of the consequences of hard rowing, running, and football playing is an increase in the size of the heart, especially of the left ventricle. While enlargement of the heart may be good enough for the youth of 22 who takes exercise freely, it is not the best for a sedentary clerk of 30. The man of 30 would find himself with more heart than he requires; his circulation would be rather embarrassed than lightened; for it is difficult to tone down the heart to the diminished needs of the economy." The lesson seems to be that excess should as far as possible be left to those who make their living by it, and it is a lesson not without application.

THE MEDICAL OFFICERSHIP OF LONDON COUNTY.

Dr. F. N. Kay Menzies is to succeed Sir William Hamer in January next as chief medical officer for the County of London. The decision was taken by the Council on Tuesday of this week. Dr. Menzies joined the medical department of the Council in 1909, and for the last ten years has identified himself with the organisation of work in connexion with tuberculosis, venereal disease, and child welfare. Eighteen months ago, with the approval of the Council, he succeeded the late Sir Napier Burnett as Director of the Hospital and Medical Services Department at the Red Cross, and two reports have already issued from his pen, showing how the voluntary hospitals of Great Britain outside London may be used to greater advantage and economy. Dr. Menzies was struck with the deficient provision for the treatment of such disorders as ophthalmia neonatorum and infantile paralysis, and he urged hospital boards to acquaint themselves with the particular needs of the area which they serve and especially to consult the general practitioner as to how they may best assist him in the diagnosis and treatment of his patients. It would, he thought, be very unfair for the Hospitals Commission to find a voluntary hospital to be failing in its duty, until it had been definitely established whether the public authorities in that area were doing their duty to those for whom they were legally responsible. He outlined a scheme for a comprehensive survey of existing facilities for the treatment of the sick, with a central bureau of hospital information. This experience and this broad outlook will now be directed towards the solution of hospital problems in London. The time is not long distant when the admirable buildings and equipment of the Poor-law institutions must be fitted into a concerted scheme for the care and treatment of the sick in the metropolis. Anyone who takes a bird's-eye view of London might be surprised to see the extent and the enviable sites of these institutions. Should they come under the jurisdiction of the Council, Dr. Menzies will have an opportunity with which we have every confidence he is competent to deal.

We have already given expression to the sincere regret felt by the very large number of medical men, hygienists, and officials, who have come into relations with Sir William Hamer, at his impending retirement. The blow will be mitigated by the Council's decision to retain his services for a further two years in a consultative capacity. Sir William Hamer entered the service of the Council in 1892 and has thus served the Council continuously for nearly 34 years. One of the most important developments with which Sir William Hamer has been associated has been the growth and organisation of the school medical service. When he took up his appointment in January, 1912, the scheme of medical inspection and treatment was in its infancy. Under his control it has become a far-reaching undertaking, under which every year 300,000 children are medically inspected, the same number are seen by school dentists, over 1,000,000 examinations are made by the school nurses in connexion with the personal hygiene scheme, 230,000 children make 1,500,000 attendances at hospitals and treatment centres, and over 100,000 attendances are made at cleansing stations. The activities of the school medical service during this period have resulted in striking improvements in the health and physique of the children in the schools. On the epidemiological side of his work, the General Purposes Committee of the Council has put on record: "Sir William's researches into the incidence of infectious diseases have made him one of the most distinguished of authorities upon epidemiology. In particular his work upon typhoid fever and upon influenza and its associated group of diseases has furnished a series of brilliant reports to the Council, and has contributed materially both to establish clearer conceptions of the nature of these diseases, and to open up new lines of preventive measures." This is no more than Sir William Hamer's due, for it is rare indeed to find a sanitary officer loaded with administrative duties who yet keeps a mind ever fresh in the pursuit of epidemiological problems. Some of these problems are appreciably nearer solution for his life-work.

At the Royal Society of Medicine the first Social Evening of the session will be held on Tuesday next, Oct. 27th, at 8.30 p.m., when the President, Sir StClair Thomson, will give a short address on Shakespeare as a Guide in the Art and Practice of Medicine.

At the Royal College of Physicians of London on Oct. 19th, after delivery of the Harveian Oration by Sir Frederick Mott, the Baly Medal was presented by the President to Prof. R. Magnus, of Utrecht. The Harveian Dinner was held in the evening, Sir Humphry Rolleston presiding. In regard to future arrangements the Bradshaw lecture, by Dr. Edwin Bramwell, on the Myopathies (Nov. 5th), and the FitzPatrick lectures, by Dr. Arthur Shadwell, on Medicine in Ancient Egypt, Assyria, and Palestine (Nov. 10th and 12th), will be delivered at the College, at 5 p.m., on the respective dates. The Lloyd Roberts lecture, by Sir Arthur Keith, on Man's Structural Defects, will be given on Nov. 16th, at the Royal Society of Medicine, 1, Wimpole-street, W., at 5.30 p.m.

Coöperation in Hospital Management.—On the purely business side of hospital management, coöperation is essential from two points of view, as was clearly pointed out by Sir Arthur Stanley in his presidential address to the Incorporated Association of Hospital Officers on Oct. 16th. These two points of view concern the hospital staffs and the subscribing public respectively. The time had come, Sir Arthur Stanley said, when hospitals must be considered to be business concerns, certainly to the extent of their administration and management, and as such they must be conducted upon the lines found to be most efficient in the business world. During the past year the Association had been invited by the King Edward's Hospital Fund to consider and report upon the proposed draft revision of the Revised Uniform System of Hospital Accounts, a revision which all were agreed was essential. Further, he stated that the Council of the Association had been most energetic in their efforts to secure the introduction of a pensions scheme for hospital officers. A concrete scheme was prepared in conjunction with one for nurses by the College of Nursing; with its adoption in London it would spread to the provinces, and they looked forward to the time when there would be one pensions scheme in operation for the staffs of all voluntary hospitals. Thus coördination in hospital management will greatly enhance the harmonious and effective functioning of the hospital system as a whole. Of hardly less importance is the effect of good business management on the subscribing public. The public wants business methods, said the President, because it wants to feel that its money is being efficiently used. A good balance-sheet is perhaps the strongest appeal that a hospital can issue.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLXIV.

TREATMENT OF HYDROCELE, HÆMATOCELE, VARICOCELE, AND SPERMATOCELE.*

III. *Varicocele.*

The ætiology of the varicose condition of the veins of the pampiniform plexus which is known as varicocele is often obscure, though its more frequent presence on the left side of the body suggests that the right-angled opening of the left spermatic vein into the renal renders its radicles more liable to obstruction than the sloping opening of the right spermatic into the inferior vena cava, and the condition is undoubtedly aggravated in constipated individuals by the drag of the loaded sigmoid colon and rectum, compressing and distorting the left spermatic vein as it crosses the pelvic brim just behind the pelvi-rectal junction. Varicocele may occur secondarily to neoplasms of the left kidney obstructing the venous return into the left renal vein, or to carcinoma of the pelvi-rectal region causing similar congestion, while more rarely retroperitoneal teratomata or sarcomata may cause varicosity of one or both pampiniform plexuses. In every case, therefore, especially where the history of onset of the varicocele is sudden, the urine should be examined for blood and the abdomen carefully palpated. Should one of these primary causes be discovered it obviously calls for urgent treatment by removal, if possible, when the secondary scrotal condition will certainly improve.

In the majority of cases, however, unilateral varicocele, usually left-sided, exists with no obvious cause, even constipation being absent; and in these cases it cannot be too strongly urged that no treatment is called for unless the condition is causing pain and discomfort to the patient. Unless his attention is directed to it, and his mind disturbed by unfounded tales of danger of impotence if the condition be left untreated, he is rarely troubled by its presence. In some few cases, especially in hot countries and in patients taking riding exercise, if the scrotum be pendulous, pain and a congested feeling result from exertion, and it is then, as also in candidates for the services, where a varicocele may be used as a cause of malingering, justifiable to interfere.

In elderly patients all that is usually necessary is a well-fitted net-suspender to support the scrotum against the perineum; this need be worn only during the day, and is a source of comfort to the patient. Suspenders are not to be recommended in the case of neurotic young men, as their presence tends to concentrate the patient's attention on the genitalia. In those cases where a suspender is ill tolerated, or where the patient is a candidate for one of the services, operation may be undertaken and the main mass of the pampiniform plexus ligated.

Operation.

The pubes having been shaved and purified, the patient is anæsthetised, and a short incision made upwards and outwards from the pubic spine on the affected side so as to expose the spermatic cord as it passes out of the external abdominal ring and down into the scrotum; there is no need to open the inguinal canal by incising the external oblique aponeurosis. The cord is elevated on a retractor, and the fascial sheath around it opened longitudinally, the cremaster muscle-fibres separated, and the vessels exposed. The vas deferens, lying behind the main mass of the pampiniform plexus, should be isolated together with the deferential artery and veins which closely accompany it. The veins are now held up on the retractor and search made for the spermatic artery, with which are usually associated one or two smallish veins; when found this also should be isolated together with the accompanying veins, but no very prolonged search should be made for the vessel, as although its ligation is not desirable, actual atrophy of the testis rarely follows. The remaining veins of the plexus are now dissected clear of the vas and artery for about two or three inches, ligated at the upper and lower limits of the cleared space, and the intervening mass removed, care being taken not to cut them within a quarter of an inch of the ligature for fear of this slipping off. A stitch is now passed through the parts of the veins distal to the ligatures, and these are approximated, a proceeding which holds up the testicle and saves the patient much discomfort and the need of a post-operative scrotal support. I do not consider it necessary to evaginate the testis through a slit in the tunica vaginalis, as the occurrence of a hydrocele of the tunica vaginalis, consequent on the cutting off of the venous return, is so rare if the operation is carried out as described above. The patient should be kept in bed for five or six days, after which he may be allowed up wearing a well-fitting net-suspender, which must, of course, be fitted after the operation. The use of this suspender is a great comfort to the patient for the first fortnight after operation, when its use should be discontinued, except in cases where the patient is indulging in occupations, such as riding or bicycling, where friction occurs to the scrotum and perineum, when the suspender should be worn for at least a month after operation, on all occasions when such exercise is indulged in.

IV. *Spermatocele.*

A further condition of interest in connexion with abnormalities of the scrotal contents is that of spermatocele, a condition usually met with in elderly men and frequently bilateral, the patient's attention being drawn to the presence of an abnormality by a sensation of fullness and discomfort in the testes. The condition arises from the blocking of the ducts of the epididymis, with subsequent distension of the tubules behind, so that one or more rounded cystic swellings occur in the course of the epididymis, usually around the upper and back part of the testes, and may be found to vary in size from a pea to a chestnut; occasionally such a swelling may arise from distension of the vestigial hydatids of Morgagni at the upper end of the testes, in which case they may be seen in younger subjects.

Treatment consists in excision of the thin-walled cysts from the surrounding epididymis, an easy task if no inflammatory reaction is present, the testis being exposed through an inguinal incision as for hydrocele. The tunica vaginalis usually needs incision to expose the cysts, and it is wise to leave it evaginated as described in order to obviate the risk of a hydrocele consequent on the handling at operation. The condition of spermatocele is not in itself dangerous, but removal of the tense cyst causes both physical and mental relief to the elderly patient, and is therefore advisable, although recurrence, usually from formation of new cysts, is by no means uncommon. Operation on both sides is liable to be followed by sterility, though it is somewhat comparable to Steinach's operation in that it is often followed by a temporary improvement in both general and sexual power.

Philip H. Mitchiner, M.D., M.S. Lond.,
F.R.C.S. Eng.,
Surgeon to Out-patients, St. Thomas's Hospital;
Surgeon, Royal Northern Hospital, London.

Naval Medical Compassionate Fund.—At the quarterly meeting of the directors of the Fund held on Oct. 6th, Surgeon Vice-Admiral Joseph Chambers, C.B., C.M.G., Medical Director-General of the Navy, in the chair, the sum of £124 was distributed among the several applicants.

Special Articles.

SCOTLAND.

(From our own Correspondent.)

James Mackenzie Institute for Clinical Research, St. Andrews.

At a meeting of the Institute on Oct. 13th Dr. Douglas Guthrie (Edinburgh) introduced the subject of prognosis in middle-ear suppuration. Though this is known to be a common condition he believed that it was often overlooked. Pus did not flow from the ear in all cases and might be small in quantity so that the disease was frequently undiagnosed. That common type of deafness, otosclerosis, was held by some authorities to be the result of previous inflammation in the middle ear which might have escaped notice. He was convinced that a proportion of deaths attributed to "meningitis" owed their origin to middle-ear disease. In many cases persistent otorrhœa resulted in chronic ill-health, while secondary pulmonary and digestive diseases were common. He alluded to the unsatisfactory terminology in use in regard to otitis media, commenting on the vagueness of meaning of such terms as "acute" and "chronic" and "catarrhal" otitis media, all of which merely represented degrees of the same process. He directed attention to several anatomical features which affected the nature and progress of the condition—e.g., the occurrence of bony pockets in the middle ear, the short, wide, straight Eustachian tube of infants, and so forth. In this connexion he emphasised the danger of common cold in the infant. He referred to cases of unexplained pyrexia in children in which, in spite of a normal appearance of the drum, pus was proved to be present on paracentesis (so-called latent otitis media). The bulk of Dr. Guthrie's paper dealt with the results of an investigation of the subsequent history of 345 cases of otorrhœa over a period of years, which was undertaken on the instigation of the late Sir James Mackenzie. This had proved most illuminating. The ultimate results of various operative procedures as regards life and deafness were illustrated, and as a result of comparison of these it became clear that the more radical forms of surgical procedure should be discarded in favour of more conservative methods. From his figures it was also evident that deafness was more commonly the result of previous middle-ear inflammation than was supposed.

Anderson College of Medicine, Glasgow.

The formal opening of the winter session took place on Tuesday, Oct. 13th, when Mr. Alexander Miles, secretary to the Royal College of Surgeons, Edinburgh, gave an address on Coördination in the Study of Medicine. Mr. Miles pointed out that the purpose of the medical curriculum, as drawn up by the licensing authorities and approved by the General Medical Council, was to qualify men and women for the practice of the profession of medicine as family doctors. In the earlier scientific subjects the student learned something of the great biological, chemical, and physical laws, and by his own observations and experiments was able to verify at least some of them. This paved the way for exact study of the human body, by means of anatomy, physiology, and pathology, with pharmacology as the equipment for treatment of morbid conditions. Hospital work followed with medicine, surgery, and midwifery, and here the student first dealt with the human subject as a sick person. Public health and medical jurisprudence taught him his relations and duties to the community as a whole. On the motion of Prof. Carstairs Douglas, Dean of the College, a vote of thanks was accorded Mr. Miles, who was afterwards entertained to lunch by the governors and staff in the Central Station Hotel.

Edinburgh: Prof. John Fraser's Inaugural Lecture.

Prof. John Fraser, who was appointed Regius professor of clinical surgery at the University of Edinburgh in March of this year on the retirement of Sir Harold Stiles, recently delivered his inaugural lecture in the anatomy lecture theatre of the University. Principal Sir Alfred Ewing presided. Under the title of "De Novo," Prof. Fraser spoke on the course he would wish his education to follow were he given a fresh start, or in other words, on his educational ideals. He said that he had regretfully to confess that with every year the profession of medicine became more of a science and less of an art, and that to keep abreast of the times in medical teaching grew increasingly difficult. In this age of specialisation the medical curriculum made such demands upon the student that there must be specialisation in the preparation for it. The education of the average student when he entered a university was deficient in one vital aspect—he had never been taught the logical processes upon which the acquisition of knowledge was based. The science of induction, observation, elimination of the irrelevant and inference were a closed book to him, or, if he used them, it was as a blind and purposeless instrument which bore no fruit because it was never enriched by the stimulus of purpose. From bitter experience he would say that that was a matter of the most extreme importance. Between man and man there was little material difference where the mental machinery was concerned; it was the manner by which it was worked and the method on which it was treated that spelt the difference between success and failure. He would suggest that the most productive course for the later school years would be a liberal general education, a sufficient knowledge of Latin and Greek to enable the student to understand the etymology of his profession, as perfect a knowledge as it was possible for him to acquire of French and German, and progressively intensified instruction in the basic or natural sciences—physics, chemistry, and biology. On leaving school he considered it a great advantage for a student to take an arts course before embarking on the study of medicine, because, in the words of Sir George Newman, it was "essential to his proper professional education that it should be deeply infused and inspired by the broadest and most liberal culture, from which he may derive mental discipline, the scientific habit, and an intellectual mastery of the principles involved in his profession." Were he again a medical undergraduate, Prof. Fraser said, he would desire to be taught analytically, he would welcome the extended use of the revision and tutorial class, and he would like to see note-taking at lectures abolished, its place being taken by printed synopsis slips distributed the day before. If medicine was once the foster-mother of science, Prof. Fraser concluded, science was now the mother of medicine, and a medical career, preparatory, undergraduate, and postgraduate, must therefore be planned scientifically.

IRELAND.

(From our own Correspondent.)

The Health of Belfast.

The annual report for 1924 of the medical officer of health for Belfast is, on the whole, satisfactory reading. The birth-rate was 23·9, a decrease of 1·1 as compared with the preceding year, when the rate was 25·0. The death-rate was 14·3 per 1000, an increase of 0·5 compared with the year 1923, but 2·8 below the average rate for the ten preceding years. Of the total deaths registered, 1948, or 30·78 per cent., were caused by chest diseases, 605 being due to phthisis, 623 to pneumonia, and 720 to other diseases of the respiratory system; 107 deaths of children under 1 year old per 1000 births were registered during the year. This is an increase of 6 per 1000 compared with the preceding year. Epidemics of scarlet fever and of encephalitis lethargica occurred during the year; 1818 cases of the former were registered with 57 deaths, a case-mortality of 0·44 per cent.; 221 cases of the latter were registered with 30 deaths, a case-mortality of 14·2 per cent. The epidemic of encephalitis lethargica was almost confined to the months of May, June, and July. No case of typhus fever was registered during the year; 44 cases of typhoid fever were registered with 3 deaths. The number of deaths registered during the preceding year was 4, and the average number registered annually during the ten years 1914–23 was 20. The disease, formerly very prevalent in Belfast, is rapidly dying out, due mainly to the city's excellent water-supply. The various health services have been well maintained. Maternity and child welfare work has been steadily developed. There were six centres in operation during the year. The number of babies medically examined was 2239, and the total number of attendances at the centres was 29,903. This work is progressing in a satisfactory manner, and its utility is becoming more and more recognised. Infant mortality remains too high, though there has been a marked decline in the last 20 years. The figure in 1904 was 154, and in 1905 it was 136, compared with 101 in 1923 and 107 in 1924. It is worthy of note that the birth-rate has fallen from 33·4 per 1000 in 1881 to 23·9 per 1000 in 1924.

Royal Victoria Hospital, Belfast.

The opening address of the present session was delivered in the King Edward Hall of the hospital on Oct. 15th by Prof. C. G. Lowry, who recalled the history of the hospital, its large developments in recent years, and the rapid growth of the Belfast Medical School. He emphasised the great importance of clinical studies, and expressed the opinion that the three years allotted to these studies were insufficient. The medical student should remember the motto of Sir Spencer Wells, "Do to-day's work to-day," and the words of Sir William Osler, "Do the day's work well, and take no thought for to-morrow." Carlyle had admonished them "not to see what lies dimly at a distance, but to do what lies clearly at hand." The lecturer stressed the importance for the student of taking careful clinical notes, which should be brief. It had been well said that "to study the phenomena of disease without books is to sail an uncharted sea, while to study books without patients is not to go to sea at all." The lecturer urged the importance to the student of the study of medical biography. It was not fitting that the medical student should know the name of Donoghue's Derby mounts but know nothing of Dupuytren or Dover, or be more familiar with the names of Lenglen and Lacoste than those of Lister and Laennec. The memoirs of Sir James Paget and of Pasteur were to be specially commended. They formed a medical and scientific history of the greatest period of progress in the history of mankind—the Victorian era. Those who were beginning their clinical studies at the present time were fortunate. Their art was at a most interesting period of its development. During the past quarter of a century there had been great advances in the knowledge of bacterial infection, venereal diseases, disorders of metabolism, X ray diagnosis, the art of anæsthesia, and the technique of surgery and obstetrics. Some of them might see the conquest of malignant disease, the elucidation of cardiovascular degenerations, and a reduction in maternal mortality in childbirth. Where the vanguard camped to-day, the rearguard would rest to-morrow. Let them always remember that courage, discipline, and perseverance were the keys to success in life.

A memorial tablet to the late Dr. J. W. Mullen has been placed in the Ladywell Sanatorium, Eccles New-road, Salford. Dr. Mullen was medical superintendent of the institution for 42 years.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Safety of Railway Travellers.

THE Academy of Medicine recently received a communication from the managing committee of the French railways asking whether the Academy had ever passed a recommendation dealing with the protection of travellers against accidents, in so far as such protection lay within the province of medicine. It appears that the Academy issued only one such recommendation in 1922, and that dealt merely with urban traffic, particularly motor omnibuses. During the last few years the number of trains, especially of express trains, has increased, and the heavy demands on the working staff calls for employees of the best type, with first-class eyes and ears, and who are decisive and quick in judgment. Alcoholism is now on the increase, and although the incidence of syphilis has apparently diminished since 1918, there is at the present time a likelihood of some increase of general paralysis of the insane, for syphilis, although promptly and efficaciously treated, was rife during the war. It is of prime importance that responsible employees such as guards, signalmen, and pointsmen, should be selected with care, and be examined exhaustively as regards their mental and physical equipment. The Academy has therefore nominated a commission, on the proposal of Dr. Maurice de Fleury, consisting of a medico-legal expert, two surgeons, a cardiologist, a neurologist, a psychiatrist, an oto-rhino-laryngologist, and an ophthalmologist. The value of the ophthalmologist is very great, for apart from testing the visual acuity of those, such as engine-drivers, in whom it is a sine qua non, he may be the first to detect the presence of an Argyll Robertson pupil, and thus be led to suspect an early affection of the central nervous system.

Hydatid Cysts of the Pancreas.

Mr. Auvray recently made a communication to the Academy of Medicine on a case which had come under his observation, the pathological interest lying in its rarity. Very few cases of hydatid cyst of the pancreas are recorded in medical literature. Dr. Vegas and Dr. Cranwell, of Argentina, record one instance of pancreatic cyst among 1700 cases of hydatid cyst, and Teichman, in a total of 2452 echinococcus cysts, found 3 in the pancreas. Dr. Villar, of Bordeaux, described in a paper read in 1905 before the Surgical Congress some 13 cases; 6 were discovered post mortem and 7 were operated upon. In 1912 Hauser collected 28 cases, of which 11 had been operated upon with 1 death, and 17 were revealed post mortem. Since Hauser's work 6 cases have been recorded, which brings the total, including Auvray's case, up to 35, of which 17 were diagnosed and operated upon. Distinction must be drawn between cysts originating in the pancreas and those which, arising elsewhere, come into association with that organ by contiguity. Six cases of the latter variety are included in the above statistics. Cysts in the tail of the pancreas are quite exceptional; the majority develop at the level of the head.

Surgical Treatment of Angina Pectoris.

Dr. Danielopolu and Dr. Marcu, of Bucharest, communicated to the Academy of Medicine the results of their observations on the modification of the electrocardiogram caused by excision of the stellate ganglion after ligature of the coronary arteries. When the myocardium has been weakened by occlusion of the coronaries, the excision of the stellate ganglion causes modifications of the electrocardiogram which are of very serious clinical import. Bearing in mind that by the excision of the stellate ganglion the majority of motor nerve fibres and certain coronary vaso-motor fibres are put out of action, and comparing experimental results with the frequently fatal phenomena of myocardiac insufficiency caused by removal of the ganglion, it must be concluded that this surgical procedure may be dangerous in many cases of angina pectoris. The researches of the two Roumanian doctors show that while the excision of the first thoracic ganglion produces important effects on the electrocardiogram, removal of the superior cervical ganglion effects no change. This fact proves that the modifications following excision of the first thoracic ganglion are caused by the blocking of the cardiac motor fibres. Jonnesco's operation consists in the removal of the stellate ganglion along with the cervical sympathetic; but the clinical and experimental results of Danielopolu and Marcu, along with operation results already recorded in medical literature, lead to the conclusion that the stellate ganglion should not be interfered with in this condition. The operation proposed is as follows: excision of the cervical sympathetic, leaving the superior cervical ganglion and the first thoracic ganglion, resection of the vagus and all its branches which supply the thorax, resection of all the rami communicantes uniting the inferior cervical ganglion and the first thoracic ganglion to the lowest cervical nerves and the first dorsal. The advantage of this operation is that while a large number of cardio-aortic sensory fibres are resected, the important afferent fibres which pass through the stellate ganglion remain unimpaired.

Conference on Hereditary Syphilis.

Speaking at a dinner held in connexion with the conference on hereditary syphilis, Mr. Durafour, Minister of Labour, Hygiene, and Social Welfare, stated that every year in France syphilis caused 40,000 abortions, 20,000 deaths among infants, and 80,000 deaths among adults. Moral progress, however, has taken place, he said, and syphilis is no longer regarded as a disease to be hushed up. As regards treatment, every day brought forth some new remedy. The campaign was becoming organised, but the State could not at present grant more than 4 million francs annually for this purpose, and there were only 450 organised centres in France.

An Index of Scientific Journals.

Although Paris abounds in large and rich libraries, it is often a very difficult matter for the research worker to know just where is filed the special scientific journal he seeks. Thanks, however, to Mr. Alfred Lacroix, permanent secretary of the Académie des Sciences, this difficulty has been removed. He conceived the idea of compiling a general inventory of the scientific journals available in the Paris libraries, indicating where each journal could be consulted. The first section of this index appeared last year, and the second, from M to Z, has just been published. The journals are classified alphabetically according to the first letter of their titles. With the help of MM. Léon Bullingaire and A. Richard, Mr. Lacroix has collated more than 17,000 journals, defunct or extant. A third section of the work will be published in a few months, containing geographical and analytical tables, to assist the inquirer who is not sure of the exact title of the journal he requires. The index is on the same lines as, but of wider scope than, the excellent index which Prof. Leiper has dedicated to those who have made the weary pilgrimage of your London libraries.

BERLIN.

(From our own Correspondent.)

Visit of Spanish Medical Men.

A party of leading Spanish medical men recently visited the medical institutions of Germany. They travelled from Cologne and Hamburg to Berlin where, notwithstanding the holidays, a special meeting of the united medical societies was convened in their honour, Prof. Kraus, President of the Berlin Medical Society, being in the chair. The Dean of the Berlin Medical Faculty and President of the Pathological Society, Prof. Lubarsch, welcomed the guests in a Latin address; Prof. Ferran, of Madrid, read a paper on the mutation of the Koch bacillus and the prophylactic vaccination of children against tuberculosis which had given favourable results. A report on the study of medicine and scientific research in Spain was given by the leader of the Spanish medical men, Prof. Rosell, of Barcelona. The party then visited the home for tuberculous children, the infants home, the Westend and Virchow Hospitals, and the Robert Koch Institute. Although a great number of medical men were away on holidays the meeting was well attended, as was the dinner at which the Spanish doctors were entertained before they left Berlin for Munich.

A Plea for Modern Dress.

The modern fashion in dress has been the subject of many and severe criticisms in this country by moralists, women's associations, and the clergy of every religious denomination because of its alleged indecency. Prof. Friedberger, of Greifswald, however, has taken up the cudgels on behalf of the modern girl, for, speaking as a hygienist, he has recently stated that modern fashions for women are almost ideal and in every respect preferable to male attire. The modern fashion not only allows free access of air and light to the body, but it has an educational influence by compelling women of every class to extend their ablutions beyond the hands and face. The advantage of the modern shoe, which only covers the heel and the toes, leaving the other parts of the foot free, is that the perspiration evaporates easily. Short frocks and very thin stockings of porous material expose the legs to the salutary influence of the sun and the air, while arms, neck, and shoulders, which have no cover at all, benefit in proportion. The "bobbed" or "shingled" coiffure, which has replaced the former fashion of wearing great masses of hair and artificial tresses, together with the light modern hat made of thin straw or felt, leads to good ventilation of the head. With the disappearance of the corset chlorosis has become almost unknown among the rising generation. Chills are less frequent in women than in men. The dress of men, notwithstanding the increased amount of physical exercise now taken, has not undergone such a radical revolution as that of the female sex. It is true that the high collar and the starched shirt have disappeared except for evening dress and that shoes have taken the place of boots, but the high waistcoat still exists. Prof. Friedberger makes proposals for reform which, however, will probably not meet with the approval of fashionable circles. Instead of long trousers, breeches should be generally worn in summer, as is already the mode for sporting purposes. A combination of shirt and pants similar to that worn by ladies should become the rule. A collar, even a soft one, Prof. Friedberger holds, is highly unhygienic and should be replaced by a sort of decolleté. Sporting dress should be generally worn in offices and for visits. Prof. Friedberger found that the dress of his assistant weighed 3229 g., while his wife's clothes weighed only 741 g. There is no reason why in an office the clerks should wear dress which is five times heavier and 20 times less hygienic than that of their lady colleagues.

A Penholder in the Abdominal Cavity.

Before the Surgical and Gynæcological Society of Hamburg Dr. König showed the case of a woman, 42 years of age, who had had several normal births and miscarriages. The last normal birth had happened one year ago. In the spring of this year a miscarriage had occurred and a putrid fœtus was removed by a medical man. She was conveyed with high fever to the Hamburg General Hospital where, besides the symptoms of abortion, a tumour of the uterus was found. It was believed that a myoma of the uterus infected by the septic abortion was present and the uterus accordingly removed. In the course of the operation, however, a piece of vulcanite penholder, 4 cm. in length, was found between the bladder and the uterus. The woman admitted that she had introduced the penholder into the uterus four years ago to produce abortion. The penholder had obviously penetrated the wall of the uterus into the peritoneal cavity. It is remarkable that a foreign body remained within the peritoneum for four years without producing any symptoms and without preventing subsequent normal births until it was detected in the course of an operation.

A Curious Verdict.

A well-known alienist had been asked by the family of a patient to give a certificate of insanity for the purpose of a divorce. He did so and charged a fee of M.1000 (£50), which was paid. As the certificate was eventually not required in the suit, the family asked the medical man to refund part of the fee, which he, of course, declined to do. The family accordingly prosecuted the medical man before the special Anti-Usury Court, alleging that the sum charged was too high. The defendant pleaded that the case had been a specially complicated one, that he had to examine the patient on three occasions for several hours at a time, and that his certificate was based on scientific deductions. In spite of these facts the court gave a verdict against the defendant because the fee was held to be not in accordance with the service rendered, and that the case thus fell under the Anti-Usury Act. The medical man was condemned to refund M.700, and moreover, in addition a fine of M.150 (£7 6*s.*) for usury was imposed. This verdict has aroused much interest because the provisions of the Anti-Usury Act are directed against overcharging for food, clothes, and other necessaries, and therefore according to this ruling a medical certificate falls into a category that appears a little strange.

PUBLIC HEALTH ADMINISTRATION.

ADMINISTRATIVE MACHINERY.*

(*Continued from p. 773.*)

IX. Japan.

The Empire of Japan covers an area of 236,000 square miles and has a population of 80 million (339 persons to the square mile). There are four large islands and over 4000 small ones.

Central Health Organisation.

The first body created in Japan for sanitary administration on a scientific basis was the medical bureau which was established at the Department of Education in 1873. Before this time there were hardly any health regulations; the "Medical Code," which was drafted in the following year, was the first unified medical statute. In 1875 the bureau was transferred to the Home Department, and since then the Ministry of Home Affairs has been responsible for the health services. The Sanitary Bureau, as it is now called, manages all the general sanitary administration except industrial hygiene, which comes into the sphere of the Bureau of Social Work. It is divided into a public health section, a medical section, and sections for the prevention of chronic and of acute infectious diseases. There are 19 members of the staff of the bureau under a director, and there are another 19 officers who act in a temporary capacity as experts. These figures include clerks. School hygiene is in charge of the Ministry of Education; the Navy and War Departments also have medical bureaux, whilst railway and prison sanitation come under the control of the Ministries of Railways and Justice. Besides these administrative bodies there are three advisory councils—namely, the Central Board of Health, the Council for the Investigation of the Japanese Pharmacopœia, and the Board for the Investigation of National Hygiene. The principal function of these bodies is to frame advice in response to inquiries made by the administrative departments, but they may put forward their views without being consulted. The Board for the Investigation of National Hygiene, which is under the chairmanship of the Minister for Home Affairs, is not a duplicate of the Central Board of Health, but is occupied in considering new measures which may be required by the unsatisfactory state of the public health. The Central Laboratories include the Infectious Diseases Investigation Institute, attached to the Imperial University, which manufactures sera, vaccines, and the like; the Hygienic Laboratories at Tokio and Osaka, which are responsible, amongst other things, for the examination of drugs; and the Research Institute of Nutrition. All of these are under the supervision of the Home Department.

Local Health Organisation.

The provincial bodies for sanitary administration are the local governors, chiefs of police stations, and chiefs of cities, towns, and villages, in addition to custom house and port quarantine authorities. In provinces the governors are the highest officials, and under them are the police departments in which are established sanitary sections to take charge of health affairs. To each of these sanitary sections experts of various kinds and a laboratory are attached. In the Tokio prefecture responsibility for sanitary administration is divided between the Governor and the Inspector-General of the Metropolitan Police, but it devolves mainly on the latter, and there is a sanitary department in the Metropolitan Police Board. The intermediate provincial authorities in Japan are the heads of subprefectures and the chiefs of police stations. As a rule, however, sanitary affairs are supervised by the chiefs of police stations, who generally have jurisdiction over subprefectures and cities, and look after health conditions therein. Cities, towns, villages and their heads have also public health responsibilities of their own, in accordance with the laws and regulations. Most cities and towns have a sanitary department and a hygienic laboratory, but in villages certain officials represent the whole health organisation. There are six ports with permanent health quarantine organisations, and the customs authorities take charge of the procedure. If temporary quarantine is needed provisional quarantine stations may be set up, and these come under the supervision of the local governor and the immediate charge of the chief of the police department of the prefecture concerned. Rural sanitation has been very elementary, and measures are being devised for its improvement on the basis of elaborate investigations which have been undertaken; but these are still incomplete. In large cities there are municipal disinfecting stations, which despatch sanitary squads for domestic disinfection. In the villages the work is undertaken by the local sanitary official, and there are lecture courses for such persons to instruct them in the work. There are regular factory inspectors attached to the staff of local governors, and a great many private organisations are interested in improving industrial conditions.

Hospitals, Schools, and Training.

Hospitals are at present controlled by the regulations of the local prefectures rather than those of the Minister. At the end of 1913 the available beds were accounted for as follows: general hospitals—public 7628, private 48,884; hospitals for infectious diseases, 25,037; isolation wards, 74,910; and hospitals for licensed prostitutes, 5000 beds. (In Japan there were over 50,000 licensed prostitutes in 1923.) The total number of beds available for tuberculosis was about 3000 in 1923, and for leprosy about 5000. The care of *schools* is in charge of the Section of School Hygiene in the Ministry of Education, and there are specialists attached to each prefectural local government. Public schools appoint school physicians, who act under the instructions of the central authorities, and private schools are following this example. Nurses are frequently employed as well. There are many training schools for *medical practitioners*, and the total number of these was over 43,000 in 1923 (7·36 per 10,000 of the population). The examinations for a practising diploma include the subject of hygiene. Midwives are required to pass an examination or take an approved course lasting two years, and there are about 40 schools of midwifery. At the end of 1923 there were over 39,000 midwives. Nursing is governed by similar regulations, but not more than one year's training is needed before application can be made to the local governor for permission to practise. There are also regulations dealing with acupuncture and moxa-cauterisation, for the practice of which four years' study is required. Much attention has recently been given to *health propaganda*, which is carried on by pamphlets, cinemas, lectures, and exhibitions, and by voluntary organisations, and there is a *Health Insurance Act*, which compels insurance by workers employed under the Factory or Mining Acts, provided that their income is below a certain figure.

---

* Based on a Series of Reports on National Health Organisation to the Health Section of the League of Nations. Obtainable in Great Britain from Constable and Co.

Statistics are collected by the Public Health Section of the Ministry for Home Affairs.

THE LONDON MEDICAL EXHIBITION.

(Concluded from page 831.)

LAST week an account was given of exhibits classified broadly under the heading of Drugs and Foods. We now deal with the following exhibits: Instruments and Appliances, Spas and Waters, and Medical Publishers.

INSTRUMENTS AND APPLIANCES.

Among the large assortment of surgical instruments and appliances shown by MAYER AND PHELPS (Chiron House, 59/61, New Cavendish-street, W.), much interest was taken in the artificial larynx for use after complete extirpation of the larynx, and in the Yates set of instruments for exploration of the nasal sinuses. A new jack for Davis's gag was also shown, and the Reavell-Moseley Electric Rotary Pump for pressure and suction was examined with interest by a large number of visitors.—DOWN BROS., LTD. (21 and 23, St. Thomas's-street, S.E.), showed surgical instruments and appliances in wide variety, many of them being made in stainless steel. The exhibit included the "Up-to-Date" Operation Table with oil pressure pump for raising and lowering, Carruther's Saline Infusion Apparatus, and Keynes' Blood Transfusion Apparatus.—JOHN WEISS AND SON, LTD. (287, Oxford-street, W.), who make a feature of rustless steel, had a good display of general surgical instruments and consulting-room lamps, and drew particular attention to May's electrical ophthalmoscope.—HOLBORN SURGICAL INSTRUMENT CO., LTD. (26, Thavies-inn, E.C.), covered a wide range of surgical instruments and appliances, including Blair Bell's vulva retractor, Cumberbatch and Robinson's diathermy electrodes, mouth gags, urethroscopes, stainless steel forceps and trocars, ophthalmoscopes, auroscopes, bone drills, and so forth.—The GENITO-URINARY MANUFACTURING CO., LTD. (64, Great Portland-street, W.), in addition to a comprehensive exhibit of instruments for bladder and kidney surgery of the latest pattern, prominently exhibited instruments for bronchoscopy and œsophagoscopy, together with diathermy apparatus and apparatus for use in the treatment of venereal disease.—SURGICAL MANUFACTURING CO., LTD. (83 and 85, Mortimer-street, W., and at Glasgow, Belfast, Dublin, and abroad), exhibited medical and surgical apparatus and appliances of many kinds, together with weighing machines, couches, and sterilisers, and made a prominent feature of the Barton Sphygmomanometer.—SCHOLL MANUFACTURING CO., LTD. (1–4 Giltspur-street, E.C.), displayed in great variety foot supports and appliances for the relief and correction of acquired foot troubles, and DE VILBISS CO., LTD. (West Drayton, Middlesex, and 27, Old Bond-street, W.), a collection of medical sprays, some of which have a convenient adjustable tip.

One of the features of ALLEN AND HANBURYS, LTD. (37, Lombard-street, E.C.), large exhibit of surgical instruments and accessories was the St. Bartholomew's Hospital Pattern Operation Table with several important improvements. Among exhibits attracting particular attention were a motor blower and suction apparatus which can be run off any current, is portable, and is comparatively silent in working, and a transformer and resistance which is economical in working and can be used for many purposes. Mercury-vapour arc lamps were shown in operation and the use of the carbon arc and tungsten arc were also demonstrated.—Another firm making a special feature of artificial light treatment was GENERAL RADIOLOGICAL AND SURGICAL APPARATUS CO., LTD. (Incorporating M. Schaerer, S.A.) (204/6, Great Portland-street, W.), who showed many forms of X ray and artificial light apparatus. A powerful high-tension transformer of small dimensions called the "Peo" for use with all types of Coolidge tubes and gas tubes attracted attention, as did also the Artificial Mountain Sun Quartz Lamp, constructed to work successfully from alternative current direct. A combined couch and screening stand was also shown, and many other useful appliances. The Model X de Quervain Operation Table fitted with pump action allowed every possible position to be obtained with little exertion on the part of the operator or his assistant.—T. CLARK AND SON (69, Marylebone-lane, W.) exhibited many forms of ultra-violet ray lamps and demonstrated economical methods of using the tungsten arc. One lamp was designed for treating five children at a time with five-minute exposures. Among other apparatus of this kind attracting attention was a bath for the whole body, fitted with six lamps. The patient is enclosed by means of curtains fitted with windows that cut off the ultra-violet rays from the operator.—X RAYS. LTD. (incorporating F. R. Butt and Co., Ltd.), 11, Torrington-place, Gower-street, W.C.), drew attention to a "New" X ray outfit especially designed for cottage hospitals, nursing homes, and for general practitioners. It occupies the space of an ordinary wardrobe, is entirely self-contained, and has one control switch only. Lamps for sunlight treatment were also prominently exhibited.—KODAK, LTD. (Kingsway, W.C.), had an interesting exhibit of "Dupli-Tized" X ray films and negatives and prints demonstrating the utility of the photographic materials made by this firm.—"RADIO-COIL" ELECTRO MAGNETIC BLANKET, LTD. (4, Manchester-street, Manchester-square, W.). The appliance shown by this company consisted of a blanket the surface of which is covered by parallel spirals of wire joined in series through which an electric current can be passed. The voltage is controlled by a resistance. A specially constructed pad containing a coil of wire can be used in conjunction with the blanket to intensify the treatment at local spots. Many claims are made for this appliance in the treatment of acute and chronic diseases which can only be confirmed by trial.

CHAS. HEARSON AND CO., LTD. (68, Willow-walk, Bermondsey, S.E., 27, Mortimer-street, W., and 24, Fenchurch-street, E.C.), in addition to a wide display of biological apparatus, made a prominent feature of a new dark field condenser, combined with an arrangement for giving transmitted light, devised by Prof. L. Arzt, of Vienna. This takes the place of the ordinary condenser and can be fitted to any microscope. Reichert microscopes were also shown with combination monocular and binocular eye-tubes, the change being made by the turn of a screw. A feature of these microscopes is that they approximate in height to the monocular instrument. Another microscope of unusual interest can be affixed to a wall by a bracket, universal joints enabling the instrument to be directed to the eye, skin, or other special part of a living subject.—HERBERT E. KENDRICK (342, St. John-street, E.C.) exhibited several kinds of metabolism and blood chemistry apparatus, special prominence being given to Benedict Portable Metabolism Apparatus, designed for completing metabolism tests at the patient's bedside without analysis; the Clinical Colorimeter, for the estimations of uric acid, urea, creatinine, and sugar in the blood; and the Clinical Blood-Sugar Outfit, designed for blood-sugar determinations by medical practitioners who lack the time and convenience for preparing the solutions and putting together the necessary apparatus.—HAWKSLEY AND SONS (83, Wigmore-street, W.) showed a wide selection of sphygmomanometers, blood diagnostic instruments, recording instruments of several kinds, blood-urea apparatus, and ophthalmoscopes. The outfit for injection of insulin, as suggested by Prof. H. MacLean, was also shown, as well as the cabinet model Baumanometer standard blood-pressure apparatus.—TINTOMETER, LTD. (Colour Laboratories, Salisbury), who are the sole makers of the Lovibond patents and apparatus for colour analysis, included in their exhibit Dr. Dudley Corbett's Radiometer for use with Sabouraud's and other pastilles, a new and improved form of Oliver's Hæmoglobinometer, and Major H. St. A. Agate's Red Cell Suspensionometer.—SHORT AND MASON (Macdonald-road, Walthamstow, E., and Atlantic House, Holborn Viaduct, E.C.) showed portable and surgery types of sphygmomanometers, clinical thermometers, as well as the thermograph recording thermometer and the micro-barograph, which records most minute changes of atmospheric pressure.—G. H. ZEAL, LTD. (75 and 77, St. John-street, E.C., and St. John's-lane, E.C.), exhibited their well-known and reliable clinical thermometers, some of them designed with the special objects of facilitating re-setting, easy sterilisation, and easy reading of the index.—British Wolmuth Sanawaves Co., Ltd. (25, High Holborn, W.C.), demonstrated apparatus for electro-galvanic treatment, the Inhaling Drug and Apparatus Co. (30, Grosvenor-place, S.W.) exhibited an apparatus which enables any drug to be transformed into an exceedingly fine vapour, W. J. Wilson and Co. (2b, Hand-court and 45, Bedford-row, W.C.) showed artificial limbs, hospital furniture, and radiant heat lamps, and Pedestros, Ltd. (Roehampton House, Roehampton, S.W.), had a comprehensive display of the latest types of light artificial limbs.—Reliance Rubber Co., Ltd. (212/213, Upper Thames-street, E.C.), displayed rubber goods made by a new process which gives high tensile strength and great durability, and A. G. Sheldon and Co. (59, Weymouth-street, W.) exhibited sterilised surgical dressings and accouchement outfits in sealed tins.—The "Quicksey" Cabinet Manufacturing Co. (10, Cromwell House, Fulwood-place, W.C.) showed medical cabinets for consulting rooms and other purposes.—H. E. Curtis and Son, Ltd. (7, Mandeville-place, W.), showed a wide assortment of belts for surgical purposes, including the well-known abdominal and colostomy supports. The Curtis abdominal support is an admirable appliance for abdominal ptosis, for the protection of abdominal scar tissue during consolidation, for mobile or displaced kidney, and for different forms of umbilical and ventral hernia. This firm also exhibited Kaylene, a colloidal hydrated silicate of alumnia and Colonol, a liquid paraffin of extra high viscosity.—Domen Belts Co., Ltd. (456, Strand, W.C.), exhibited belts, bandages, and supports for pregnancy, accouchement, gastroptosis, umbilical hernia, and floating kidney.

Appliances for the deaf were shown by "Ardente-Acoustique" (95, Wigmore-street, W.) who had a wide range of different types of "Ardente-Acoustique" aids for the deaf which in their improved form are smaller and lighter than hitherto. A feature of these instruments is their inconspicuousness and their perfectly natural tone, reverberation and metallic sounds being practically absent. There is a special type for use in public buildings, while the types for personal use number 30. A special stethoscope for deaf doctors was demonstrated, and the attention of medical men was called to the fact that instruments are always allowed to be tried in their homes by patients.—General Acoustics, Ltd. (77, Wigmore-street, W.), displayed many electrical and non-electrical aids for the deaf. This firm supply the Acousticon for multiple installation for use in churches and in large gatherings. A point is made of the fact that patients are permitted to have the instruments on trial.—W. H. Pettifor (11, Victoria-street, S.W.) showed a large range of electrical aids for the deaf and a test instrument for estimating the most suitable pitch, sound-wave form, and volume of sound for each individual case.

Gas Light and Coke Co. (Horseferry-road, Westminster, S.W.) demonstrated radiant gas stoves and fires, showing at the same time the advantages of gas over coal in regard to atmospheric pollution.

Spas and Waters.

The attractive display by some of the principal spas and watering-places of this country indicated a growing activity among our balneological centres. Unfortunately the advantages of British spas in the matter of treatment is too frequently overlooked, while in these days of enforced economy travelling expenses necessitated by a visit abroad are items of importance. The demand, too, for spa treatment for insured persons added interest to the exhibits.

All the British spas advertised their advantages both for treatment and recreation by photographs, books, and pamphlets giving an analysis of the waters, the technique of particular treatments, and the organisation of the establishments. Bath provides for every form of balneotherapy and electrotherapy. The hot springs are the only ones in Great Britain which rise at a natural temperature of 120° F., and they yield every day half a million gallons of the most highly radio-active mineral water in this country.—Buxton has radio-active thermal waters at 82° F., and one of the strongest chalybeate springs in Great Britain. The thermal water emerges from the limestone rock by nine springs, which are identical in temperature and composition.—Droitwich, a natural brine baths spa, is a summer and winter resort which has many attractions, is sheltered from cold winds, and the brine which is supplied from springs 200 ft. below the town is about ten times the strength of the ocean. The treatment consists of baths and douches, in some cases in combination with massage either given under the spray in the form of massage douche baths or administered in the form of dry massage.—Harrogate has 87 springs, of which 16 are used internally, and all continental methods of treatment are available in addition to special treatments originating at this spa. Latest developments include a nose and throat department and the ultra-violet ray treatment.—Torquay, which has an equable climate, has available 60 different treatments and is equipped with all the latest appliances. Special features are the seaweed baths for muscular and articular rheumatism and the Dartmoor peat baths and packs.—Messrs. Ingram and Royle, Ltd. (Bangor Wharf, 45, Belvedere-road, S.E.), importers and exporters of natural mineral waters, salts, and pastilles, prominently displayed their bottled Vichy Célestins, Evian-Cachat, Carlsbad, Hunyadi Janos, and other waters. A pamphlet issued by this firm shows how the Contrexéville cure can be continued by the patient at home.

Medical Publishers.

Medical books were shown by :—

Adlard and Son and West Newman, Ltd. (23, Bartholomew Close, E.C.); Baillière, Tindall and Cox (8, Henrietta-street, W.C.); William Heinemann (20, Bedford-street, W.C.); H. K. Lewis and Co., Ltd. (136 and 140, Gower-street and 24 and 28, Gower-place, W.C.); and Stanley Phillips (45, Brondesbury-road, N.W.).—The Food Education Society (24, Tufton-street, Westminster, S.W.) made a feature of books and pamphlets on food cookery and hygiene, notable among them being a series of little books entitled "Facts for Patriots," dealing with the physiological and economical uses of food. These books deserve a wide publication.

The Lancashire and General Assurance Co., Ltd. (Lancashire House, 8, Bucklersbury, E.C., and Oxford, Cambridge, and London), made a special feature of their Comprehensive Medical Policy at a premium of £20 per annum, covering a complete medical indemnity with an unlimited amount for damages and cost, sickness and accident, motor-car, contents of house with full protection for servants under the Workmen's Compensation Act, and against other liabilities.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. (D) L. M. Hughes to the *Impregnable*, tempy.

ROYAL ARMY MEDICAL CORPS.

ARMY RESERVE OF OFFICERS.

Maj. E. N. Graham, late Malay States Volunteer Res., to be Maj.

TERRITORIAL ARMY.

Lt. B. G. Thompson resigns his commission.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. H. M. Brown, from the Active List, to be Capt.

ROYAL AIR FORCE.

Flying Officer W. J. Hutchinson is transferred to the Reserve, Class D2.

INDIAN MEDICAL SERVICE.

Capts. Bankim Behari Das and Ram Chand Mahajan relinquish their tempy. commns.

The King has approved the retirement of Maj. A. G Coullie.

LECTURES ON HYGIENE TO CADETS.

A course of lectures on hygiene and sanitation are to be given in each term to the cadets of the Senior Division at the Royal Military Academy and the Royal Military College by an officer nominated by the Director-General, Army Medical Services.

Royal Portsmouth Hospital.—The enlargement of this hospital has become so urgent that the governors have appointed a special committee to consider the whole question of further hospital accommodation in Portsmouth. Dr. Scott Ridout states that the waiting-list includes 19 cancer patients. Meanwhile an endeavour is being made to purchase a small property on Portsdown Hill for the provision of a convalescent home for children. It is believed that by the erection of simple chalets accommodation can be found for 50 children at a time.

THE MANCHESTER BABIES' HOSPITAL.

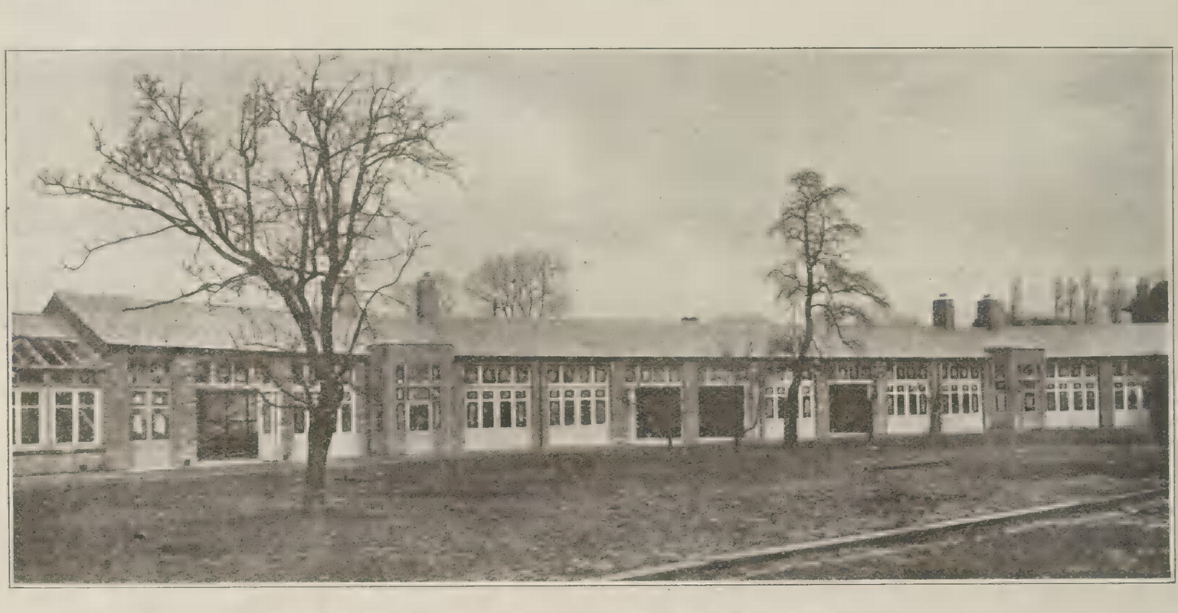
THE new buildings of the Manchester Babies' Hospital were opened on Oct. 19th by the Earl of Derby.

The hospital began its career in 1914, on the first day of the war, in a semi-detached house which accommodated 12 infants and the nursing staff. By 1918 it was already recognised as a useful training centre for welfare workers and the number of patients had risen to 30, all of them under 1 year of age. The transfer of the work to the grounds of Cringle Hall, Levenshulme, in 1920 was a further step in the desired direction, and it is here that the new buildings have been put up which will go far towards realising at last the ideals of the founders. The objects of the hospital as it now stands are three: to give institutional treatment to babies suffering from disorders of nutrition, including epidemic summer diarrhœa and rickets; to train girls in the care of infants; and to give opportunities for research into disorders of nutrition. The new arrangements are the fruit of much anxious thought and study, and they should provide a hospital which will be a model for others. Cringle Hall itself is to be used as an administrative block and for the accommodation of the three nursing mothers who supply breast milk for use in the wards; an adjoining house called Northbrook has been bought as a nurses' home, whilst the new block, which is illustrated above, is designed for the 80 patients. Twenty of these will be children below 2 years of age who are suffering from rickets or some other nutritional disorder.

The wards, ten in number, are on the ground floor, and the central four face due south. Running to south-east and south-west at an obtuse angle to one another are two large wards, and each of these ends in a smaller ward and a sun parlour whose walls and roof are mainly of glass. In a sheltered angle are two smaller rooms intended for specially delicate or premature babies, and the fronts of the wards are made with doors that fold back, so that in summer they will actually be open-air verandahs. The east and west wards have large windows behind, but to the rear of the central wards runs a corridor and on the other side of this are the bathrooms, two at each end, with the diet kitchen and dispensary in the centre. The wards are divided into units of 20 beds, and for each 20 is supplied a bathroom and changing room and large ward store cupboards, the whole being so arranged that any ward and its service can be completely isolated from the others. The divisions between the wards are of glass, and the whole length of the building can thus be easily supervised. Two baths are supplied for each 20 infants, and these baths are specially designed and fitted with spraying tables. Attached to the wards is a block containing a small laboratory and an X ray room with equipment for electrotherapy and massage.

Along the front of the hospital and at each end run concrete terraces so that the cots can be wheeled out into the sunshine: around these are lawns, with a few shady trees, and the building itself, as should be clear from the description, is specially adapted for open-air treatment. At some distance away a temporary house, with three small rooms and a bathroom, has been fitted up for the isolation of infectious cases for observation. A covered corridor connects the new block with the main building, and in this is a dining-room for the nurses and a large room for use as a library and doctor's office, where lectures may be given. Here also are the quarters of the resident medical officer and the matron, the board room, and the secretary's and matron's offices. In the adjoining house good quarters are provided for the nursing staff; there are common rooms for sisters and nurses, a study room, and a sewing room, besides pleasant bedrooms. It is believed that the conditions will be very satisfactory.

The record of the hospital is excellent and the extension of its facilities is likely to lead to useful work. During last year 223 children were treated. Dr. Catherine Chisholm, the chairman of the medical committee, has shown how the regular provision of milk from wet nurses may be placed on a satisfactory basis, and there is a good system by which a certain number of beds may be allotted to a medical woman, not on the honorary staff, who desires to gain special experience in infant work. Recently these beds have been used, under the direction of Prof. H. S. Raper, by Dr. E. F. Willock, the medical registrar, for her research on the value of oxygen administration in the treatment of atrophic infants. The hospital is a centre for post-graduate instruction, whilst its usefulness in the scientific education of nurses and welfare workers is already well known. The address is Burnage-lane, Levenshulme, Manchester.



The Manchester Babies' Hospital: The new wards before completion.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics of three cities for 1924 :—

Name of city.	Estimated mid-year population (R.G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternity mort. from childbirth.
Birmingham ..	946,980	19·2	11·6	1·10	1·30	2·5	35	83	3·9
Bradford ..	290,200	16·9	14·9	1·05	1·50	3·9	40	92	4·0
Leicester ..	241,800	18·1	12·1	1·43	1·16	2·1	29	79	3·2

Birmingham.

Sir John Robertson says the general health of Birmingham during 1924 may be considered to have been satisfactory, and that the death-rate was a low one, considering the amount of unemployment and the proportion of the people who are wretchedly housed. The death-rate, he says, is only a crude measure of estimating the healthiness of a town and the amount of sickness ought to be considered. During 1924 it was ascertained that in the public health department and in a number of industrial concerns with good working conditions the average amount of sickness among males was 10 days per annum and among females 11. In other words, about 1 employee in every 30 was permanently absent. Influenza and respiratory catarrhs accounted for from one-third to one-half of the sick absence. Sir John Robertson states that the methods of birth control are becoming widely known among young people and lead to promiscuous intercourse without inconvenient results. A knowledge of such methods also incidentally supplies information as to the prevention of venereal disease. He considers that a spread of this movement may be a serious menace to the family life of the country. The eugenic idea of improving the human stock is impossible so long as our present customs exist, and is there any reason to suppose that, granted equal environmental conditions, it would be better to breed from the upper or the lower half of society? During the past 20 years the birth-rate in Birmingham has been materially reduced, and if the rate of reduction continues for another 20 years the birth-rate will be lower than the death-rate. Sir John Robertson states the arguments in favour of large families, and thinks that since birth control is much more likely to be put into operation by the skilled artisan and middle class than by the poorest of the community, it is consequently liable to be dysgenic.

Illustrations are given in the report of a building which has been adapted for light treatment. The new Carnegie Institute has also been so equipped, and in November a light department was opened at Yardley Road Sanatorium for the treatment of various forms of tuberculosis by ultra-violet rays. Mr. W. Brennan De Vine, F.R.C.V.S., reports on tuberculosis and the milk-supply. Of 303 samples of milk from outside farms, 26 were found to be infected with tubercle. As the result of visits to the farms 23 cows affected with tuberculosis were found and slaughtered. It was not possible to trace all the offending cows because in several instances cows had been disposed of between the time of taking the sample and the visit of the veterinary inspector to the farm. Three cows were found in the city cowsheds suffering from tuberculosis of the udder and were slaughtered by arrangement with the owners. At the beginning of 1924 there were 18 herds included in the Birmingham scheme for securing tubercle-free herds. One of these herds dropped out during the year owing to the large number of reactors. Out of 129 head of cattle in this herd 37 failed to pass the test and two were doubtful. During the year ten owners applied to be included in the scheme, but three of them gave the matter up. The cows in these three herds numbered 36, 38, and 24, and the number of reactors were 23, 25, and 13 respectively. At the end of the year there were 24 herds left in the scheme, which was an increase of six over the previous year. There were 431 cows tested for the first time, and of these 223, or 51·7 per cent., failed to pass the test. The herds included in the scheme are classified according as to whether they are maintained by breeding, by purchase, or by both methods. In the case of the one non-breeding herd 19 cows were tested and eight failed to pass the test. In the case of the four herds maintained by both breeding and purchase there were 20 failures in 115 tests, 37 in 132, 19 in 53, and 2 in 21 respectively. There were 12 herds maintained by breeding; of these, 8, including 283 head of cattle, furnished 22 reactors, while 4, with 55 head of cattle, had no reactors. An investigation was carried out during the year of the methods employed by various dairymen for the washing of milk bottles. The results indicated that steaming was the only satisfactory process, and that methods of washing by hand with or without the use of some simple machinery are not satisfactory.

Dr. Ethel Cassie submits the first annual report of the Carnegie Institute, which replaces the Farm-street Centre, and has already more than justified itself. There were 145 dental clinics held, with 1883 attendances of mothers and 683 of children under 5 years of age. Anæsthetics were used 1088 times. In addition to other advantages there is an observation ward, and Dr. Cassie considers that it would be difficult to exaggerate the value of such a ward in connexion with a large child welfare centre. Encephalitis lethargica showed a greatly increased prevalence in Birmingham during 1924. There were 282 cases notified with 44 deaths. A description of the types most prevalent in Birmingham was prepared by Dr. Stanley Barnes and circulated to all the medical practitioners in the city. During May, 1925, an inquiry into the condition of the 229 survivors of acute attacks during 1924 showed that only 46 had at that time made a complete recovery.

Bradford.

Dr. John J. Buchan's report on smoke inspection shows that there were 15 prosecutions and that the total penalties and costs only amounted to £13 11*s*. He expresses his regret at such nominal fines which may well place the offending party in a better position than the manufacturers who try to do their duty. Mr. W. Halstead, the veterinary inspector, reports that the average number of dairy cows in the city is 3406, housed in 276 dairy farms. They produce about 7500 gallons of milk in the day, whilst about 7000 gallons come into the city by rail or road. Among the city cows 18 cases of tuberculosis of the udder and 8 cases of advanced tuberculosis were found. Of these 26 cows 14 were slaughtered, while 12 were removed from the city and lost sight of. No "designated" milk is produced within the city. At the municipal milk depôt over 51,000 gallons of milk were obtained from six sources outside the city, including 8760 gallons of Grade A tuberculin-tested milk. During the year 90 samples of shell-fish (65 of mussels, 20 of cockles, and 5 of oysters) were submitted to the bacteriologist; 86 of the samples were obtained at the wholesale market within a very short time of delivery by the railway companies. Of these 13 were reported to be good, 53 were reported to be bad, and 20 to be doubtful. The tuberculosis officer, Dr. H. Vallow, reports as to the unsatisfactory results which, up to now, have been obtained in the training of tuberculous ex-Service men under the 1922 scheme.

Of 35 men referred by the Ministry of Pensions to the tuberculosis officer, 16 were considered suitable for training. Of the 11 who accepted it, 8 completed their course, and the final result was that only one continued in the occupation in which he was trained. Though the results as regards work were poor, Dr. Vallow points out that the long treatment and training has had a lasting effect on the health of these men. The experience gained has also been useful, and an extensive survey of the various methods of providing employment for the tuberculous is being made. The number of new houses (694) was larger than in any year since the war; 375 of them were municipal. In addition to those completed there were at the close of the year 639 municipal houses in course of erection, and 484 houses, mostly of a superior type, being built by private enterprise. In spite of this, many very serious cases of overcrowding came to the knowledge of the department during the year, and at the close of the year applicants for new houses numbered 5493, of whom 4012 were ex-Service men, 2775 of them living in lodgings.

Leicester.

Dr. C. Killick Millard says the most unsatisfactory feature of the year's record was the serious epidemic of diphtheria which began in the third quarter and continued for several months. There were 429 cases reported with 34 deaths. The "Schick" test has not hitherto been used at the isolation hospital, and seven of the staff contracted the disease, one of the cases ending fatally. As a result the staff were inoculated before going on duty in the diphtheria wards. Subsequently two nurses and the medical superintendent had mild attacks of the disease, probably because sufficient time had not elapsed to establish their immunity. Small-pox, after being absent for 19 years (with the exception of one case in 1913), again visited the city in 1924. There were two importations resulting in five cases, all very mild. During 1925 the disease has again been introduced and, though this last outbreak has been more serious, there have been no fatalities as yet. The principal difficulty has been the prevailing mild type of the disease and the absence of many of the classical symptoms. With a view to meeting this difficulty the medical practitioners of the city have been invited to attend demonstrations at the small-pox hospital. Dr. Millard points out that the essential difference between the practice in Leicester and elsewhere seems to be that, when a case of small-pox occurs in Leicester, no effort is made to secure the vaccination and revaccination of the general population, but the use of vaccination is confined to contacts. Forty years ago, in 1885, the Leicester Board of Guardians by an overwhelming vote decided not to prosecute for default under the Vaccination Acts, and since then these Acts in Leicester have been virtually a "dead letter." Thus, during the 17 years 1908 to 1924 the percentage of infants vaccinated has been 6·7. There were 22 cases of encephalitis lethargica notified with seven deaths, as against an average of nine cases and five deaths for the four previous years. The Leicester health committee has formed a local cancer committee, which is carrying out statistical investigations and has issued a leaflet of advice to women on the subject of cancer of the breast. Under the heading "goitre" it is pointed out that two or three firms have now placed an iodised table salt on the market. Dr. Millard gives some particulars indicating a hopeful view of the "Spahlinger" treatment of tuberculosis. As regards housing, Dr. Millard states that a "very substantial measure of relief is in sight in the near future." The procedure as regards the cleansing of dirty houses is discussed, and he inclines to the view that it is better for the tenants to do their own cleaning, including whitewashing of ceilings and the treatment of the walls. In Leicester tenants expect their walls to be papered by the landlords. The recent Birmingham case is quoted in which a notice was issued by the city corporation requiring certain repairs including painting and papering, and the Ministry of Health decided that where the plastering was sound and the surface smooth the requirements that an owner shall re-paper the walls shall be satisfied if the walls are stripped, cleansed, and distempered, and that where the ceilings are not to be scraped one coat of whitewash shall be sufficient.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 10TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 34; scarlet fever, 2287; diphtheria, 1118; enteric fever, 68; pneumonia, 842; puerperal fever, 54; cerebro-spinal fever, 7; acute poliomyelitis, 12; acute polio-encephalitis, 3; encephalitis lethargica, 36; dysentery, 7; ophthalmia neonatorum, 120. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 14 from measles, 8 from scarlet fever, 20 from whooping-cough, 28 from diphtheria, and 57 from influenza, as compared with 51, 41, 26, and 11 in the preceding weeks. In London itself there were 7 deaths from diphtheria, 2 from whooping-cough, and 12 from influenza, as compared with 9, 5, 7, and 1 in the preceding weeks.

Obituary.

CHARLES FREDERICK SONNTAG, M.D., CH.B. EDIN.

Dr. C. F. Sonntag, whose death occurred at Hampstead on Oct. 10th, was born at Glasgow 38 years ago, and was educated at Edinburgh and at the Middlesex Hospital. He graduated as M.B. in 1910 and as M.D. (with honours) in 1913, and held obstetrical and surgical appointments in Scotland. Soon after the outbreak of war he joined the Royal Army Medical Corps and saw active service as regimental medical officer in several units of the Salonika Expeditionary Force. In 1916, being incapacitated by tuberculosis from further foreign service, he was invalided home and became medical officer to the Red Cross Clinic for Disabled Officers in Great Portland-street. Here he threw himself with energy into the investigation and application of the new methods of physical treatment which had been brought together, and proved his ability by his researches. He produced papers dealing with the influence of temperature on muscular work, with ergometers, and with thermal debility. Thence he was recommended as hydrologist to the Military Orthopædic Hospital at Shepherd's Bush, where he pursued his studies on stimulant and sedative baths, and though in 1919 he accepted the post of prosector and anatomist to the Zoological Society of London and took up research on comparative anatomy, he continued as a hydrologist in consultant practice.

In 1922 Dr. Sonntag was appointed demonstrator in anatomy at University College. During the six years he worked at the Zoological Gardens he published in the Proceedings of the Society no less than 30 papers on comparative anatomy, all of which bore witness to the thorough and painstaking way in which he carried out his work. His publications included a series of papers on the comparative anatomy of the tongues of the mammalia, and were mainly descriptive in form. His later papers dealt with the anatomy and physiology of the anthropoid apes, and in 1924 he summarised his findings in a treatise on the morphology and evolution of the apes and man, which will be the standard work on the subject for many years to come.

Dr. Sonntag's early death has removed a man whose critical enthusiasm has left its mark on both the subjects in which he interested himself.

RUPERT CECIL CHICKEN, F.R.C.S. Eng., L.R.C.P. Lond.

Mr. R. C. Chicken, consulting surgeon to the Nottingham General Hospital, died on Oct. 3rd at the age of 75. After studying at Guy's Hospital, he held the appointments of house surgeon and obstetric assistant there, and became registrar at the Evelina Hospital. He became F.R.C.S. in 1875, and was appointed prosector of anatomy at the Royal College of Surgeons. Later he returned to Nottingham and was unexpectedly left in charge of a large mixed general practice. His training and natural aptitude fitted him for surgery, and in spite of other work he was able to maintain his operative skill; in 1891 he was elected to the staff of the Nottingham Hospital, and in 1892 was president of the Nottingham Medico-Chirurgical Society. Mr. Chicken was the author of a long series of surgical papers, and was in addition a man of wide reading and culture, with an active interest in archæology. He retired from the executive staff of the hospital in 1907, but during the war served as surgeon to the Whipps Cross War Hospital, Leytonstone. He leaves a widow, one son, and two daughters.

HAROLD MAXWELL LEFROY, M.A. Camb., F.E.S., F.Z.S.

The science of entomology has sustained a severe loss by the untimely death at the early age of 48 of Prof. Harold Maxwell Lefroy, professor of entomology at the Imperial College of Science and Technology. Prof. Lefroy died as the result of an accidental exposure to poisonous gas in the course of experiments designed to discover a suitable method of dealing with flies and their maggots. He lay unconscious for three days and in spite of all possible medical assistance succumbed in the evening of Wednesday, Oct. 14th.

Harold Maxwell Lefroy was educated at Marlborough and King's College, Cambridge. He took the Natural Sciences Tripos, choosing zoology for one of his subjects. At that time the zoology taught in Cambridge was rather of the laboratory and formal type, and it is on record that Lefroy's attention to this aspect of the subject was but half-hearted. The passionate love of insects and their ways seems to have been born in him, and he deserted the laboratory demonstrations in order to practise "bug-hunting" in all the country surrounding Cambridge. After taking his degree, as at that time entomological posts were almost non-existent, he was forced to adopt the profession of teaching natural science in a school. But the memory of his devotion to insects was preserved by his teachers in Cambridge, and when the demand came for a man to go to the West Indies and deal with the pests which were destroying the sugar-canes there, it was Lefroy whom they recommended for the post.

After a successful career in the West Indies Lefroy was appointed as the first Imperial entomologist to the Government of India, and it was during a period of leave in England in 1910 that he was induced by the authorities of the Imperial College of Science to deliver a course of lectures on entomology. The success of this course made the governors of the College resolved, if possible, to secure him permanently, and the next year he became professor of entomology, a post which he retained until his death.

During the war his services, like those of all the rest of the College staff, were placed at the disposal of the Government, and he went to India in 1915 to investigate the silk industry, and in 1917 to Australia to deal with the pests which were destroying grain. His success in grappling with these and other pests is told in a leading article on another page. His immediate relation to medical questions was slight, but during the war, when house-flies and blue-bottles were recognised as disseminators of disease, he devoted considerable time to devising fly-traps of various kinds and measures for dealing with the maggots. It was, indeed, as we have already mentioned, during the course of experiments with gases as a means of destroying flies that he met his death. He leaves a gap in the staff of the Imperial College and in the entomological world which will not be easily filled.

EDMUND ARCHIBALD ARMSTRONG, M.A.

We record with deep regret the untimely death of Mr. Archibald Armstrong which occurred on Oct. 15th at Oxford and Cambridge Mansions in his sixty-seventh year. He had been a valued member of our staff for nearly 30 years.

Archibald Armstrong was the son of the Rev. John Armstrong, rector of Dinder and prebendary of Wells. He was educated at Haileybury, where he was captain of the school, and Jesus College, Cambridge, where he was a Rustat scholar, and at both places he distinguished himself also on the running-track. He graduated with classical honours and was called to the Bar, but turned aside almost at once to literature. He wrote stories and verses for many of the popular magazines, one series contributed mainly to the *St. James's Gazette* appearing in volume form under the title of "Tales from the Temple." This was followed by a novel with a particularly ingenious plot, "Under the Circumstances," while a play supplied to the German Reeds proved a modest success in the old Queen's Hall. He became editor shortly after of the illustrated weekly paper, *Black and White*, but his control of the paper was only partial, and he found the position untenable. During this period he wrote intermittently for various London and provincial papers, and regularly for The Lancet on the legal side of medical affairs, work which he was discharging until his death. We have many reasons for knowing that his well-informed and even pronouncements upon many difficult professional problems were of great value to our readers, while the public derived indirect advantage from much of his work. In this connexion there may be instanced a ruthless exposé of the proceedings of a dangerous group of quacks, who were defrauding women, as well as inciting them to misbehaviour or crime, by the sale of abortefacients.

In the course of general journalism he grew to be a considerable expert in certain artistic fields, with the result that he became one of the managers of the Fine Art Society's gallery in Bond-street, under the late Marcus Huish. Here he was working when the war broke out, when he entered the Censorship Department, where his duties were prolonged some time after the armistice in view of the preservation and arrangement of the records. When this work came to an end he returned to his duties at The Lancet, and also joined the staff of the *Daily Express*, to which paper he was attached at his death, while he resumed his connexion with the Fine Art Society by joining the directorate.

He had not been physically strong for some years and probably worked beyond his powers, but quite recently his health appeared to have much improved, and the announcement of his death will come as a shock to many friends and journalistic colleagues. For he was held in high esteem for his exact knowledge, his careful and accurate methods, his fairness, and unfailing courtesy. We owe him a great debt at The Lancet.

He married early in life the daughter of the late Rev. Lancelot Errington, rector of Midgham, Berkshire, by whom he had one daughter. To these we offer our sincere sympathy.

St. Mary's Hospital for Women and Children. Sir Alfred Fripp describes this hospital at Plaistow as a model as far as the in-patients' department is concerned, but in a backward state in regard to accommodation for out-patients. An endeavour is being made to improve this state of things by the preparation of a scheme which will cost £25,000 eventually, though the first portion of the work is expected to cost no more than £8000.

Correspondence.

"Audi alteram partem."

THE SANATORIUM AND AFTER.

To the Editor of THE LANCET.

SIR,—All who are interested in the solution of the tuberculosis problem will agree with your statement that "the after-treatment of ex-sanatorium patients is one of the most urgent and elusive problems which medical and social science has to face."

Many of those who have been considering for some years this aspect of the question will welcome the admission that "from the strictly medical standpoint . . . . the combination of sanatorium, settlement, training centre, and workshop offers the ideal conditions for after-care." This is the ideal for the general acceptance of which Dr. Varrier-Jones, without much outside support, has, at Papworth, been striving for years, and it will doubtless be a source of much satisfaction to him to find that the success of the pioneer work which he had carried out there has at length received public recognition. On a recent occasion Mr. Neville Chamberlain expressed his complete approval of the settlement plan and stated that henceforth it would receive the full support of the Ministry of Health.

The observation that "settlements can only deal with a fraction of the tuberculous population" should possibly have been slightly modified and to be strictly accurate should read, "are at present only dealing with," but at Papworth alone the fraction is even now ten times larger than is being dealt with under any other combined scheme with which I am acquainted, and when Preston Park, near Maidstone, which has recently been taken over by the British Legion and which at their request is now being reorganised by Dr. Varrier-Jones on Papworth lines, is reopened the fraction will be still larger. Private individuals are, of course, free to support such charitable efforts as appeal most closely to their sympathy, but with regard to public money and quasi public funds the case is different, efficiency and the welfare of the community as a whole are then the guiding principles of action.

Having had somewhat exceptional opportunities of judging of the relative value of the methods mentioned in your annotation I have come to the unhesitating conclusion that the development of settlements on Papworth lines around those of the existing sanatoria which admit of such an evolution holds out the most hopeful prospect of a continuous advance towards the solution of the problem of the after-care of the tuberculous worker, and to that end I propose to devote such energy and influence as I possess.—I am, Sir, yours faithfully,

JAMES K. FOWLER.

Clarges-street, Mayfair, Oct. 19th, 1925.

LUMINAL, BORAX, OR BROMIDE IN EPILEPSY.

To the Editor of THE LANCET.

SIR,—Concerning the relative value of luminal, bromide, and borate in epilepsy, I was interested to read of the very satisfactory results obtained by Dr. Figdor with combinations of bromide and borax. For many years my initial treatment—apart from any general treatment or psychotherapeutic measures necessary—has been to prescribe a combination of sodium bromide and sodium biborate, and it is seldom indeed that some degree of improvement is not obtained, at least in decreased frequency and severity of the seizures and in the patient's symptoms.

A start is made with 15 gr. sodium bromide and 7 gr. sodium biborate, together with 3 minims liquor arsenicalis, given morning and evening, and increasing to three times daily if improvement is not obtained. The addition of a few minims of liquor arsenicalis is useful in preventing a bromide rash. The prescription is really an old one and well established; its value would appear to lie chiefly in the bromide rather than in the borax, although the latter may assist. With borax alone, even in large doses, in epilepsy, I have never met with any success. If a good result is not obtained with the combination of sodium bromide and biborate, my experience has been that it is useless to persevere with bromides and that one must seek for another remedy.

In a contribution to the discussion on the Nature and Treatment of Epilepsy [1] at the B.M.A. meeting, Bradford, July, 1924, I gave the results of treatment with different remedies in a large number of cases of idopathic epilepsy, analysed in conjunction with Dr. H. C. Beccle. We found that several cases responded to luminal in a most remarkable manner. I am, however, in entire agreement with Dr. Williams-Walker that more than 3 gr. luminal per day is undesirable, and I stated in the above communication that my experience had been that if one did not obtain a satisfactory result with 1½ gr. luminal morning and evening the case was unlikely to respond to luminal at all. If a dose of 3 gr. per day be not exceeded, none of the unpleasant symptoms mentioned by Dr. Figdor and Dr. Carlill will be seen. In general, I have not found that luminal loses its effect after a few months, and have some cases that have been continuing on 3 gr. a day over a period of more than two years without experiencing an attack. In patients who do not show an adequate response to either the bromideborate or luminal, a combination of sodium bromide (10 to 15 gr.) and luminal (1½ gr.) night and morning will often produce a good result. In three cases so treated attacks had been entirely absent for over a year. Of other remedies, some cases—especially those in which the fits are nocturnal—respond to dialacetin (1½ gr. either at night or twice daily) when other drugs have failed.

I am, Sir, yours faithfully,

C. WORSTER-DROUGHT, M.D.

Cavendish-square, W., Oct. 19th, 1925.

UNUNITED FRACTURES.

To the Editor of THE LANCET.

SIR,—With some statements in Prof. E. W. Hey Groves's interesting address on this subject, published in THE LANCET of Oct. 10th, it is impossible for me to agree. Prof. Groves states that "unrestricted mobility" is one of the mechanical causes. This recalls vividly to my mind the case of a man with an unreduced dislocation of the humeral head. It was of several weeks' duration. In the attempt to reduce it the surgical neck of the humerus was fractured. As house surgeon my instructions were to apply no splints and to carry out passive movement at the site of fracture frequently and fully so as to establish a false joint. The proceedings were naturally very painful, and the result was absolute and strong union. This impressed me much, for at that time the teaching in fracture of the humerus was to immobilise the whole upper extremity, with even a shoulder-cap and a splint carried to the end of the fingers, lest non-union should result. This case was an example of the most unrestricted mobility that I have ever heard of.

The next statement made with which I do not agree is that "in the case of the shaft of the humerus the difficulty of efficient fixation is the prime cause of frequent non-union." Much depends on what is meant by "efficient fixation." In any arm it is impossible to apply splints that will in any way absolutely control the fragments from movement. That is the case in all fractures. How much more so when the arm is swollen with the effused blood. There is only one way to produce immobility and that is open operation. There is no need, however, for any operation, nor do patients want an operation if they will get equally good results without and no likelihood of non-union. Personally I am unaware of a case of non-union of the humerus where the principle of active movement has been adopted from the first. There has been only one case of delayed union to my knowledge, and that took six months to solidify. It was treated by making the patient tap her elbow frequently on a firm cushion, with the humerus straight up and down, and otherwise using it as much as she could. Such is the record for simple fractures, and in septic fractures I have not had a case either, though many came under my care with gaps and foreign bodies during the three years I was in charge of wards at the Edinburgh War Hospital, Bangour.

---

[1] Brit. Med. Jour., 1924, ii., 1054.

The last statement with which I do not agree is that " The importance of mobility as a cause of non-union has been obscured by the teaching of those who advocate early movement of a limb as conducing to rapid restoration of function." If Prof. Groves had seen and followed the wonderful results obtainable by early active movement he would probably have been much less drastic in his remarks. It is close on 25 years since I adopted the method of treating fractures of the upper extremity by early active movement *short* of pain and gradually increasing the movement. No splints are employed unless some obvious gain will result. Naturally the upper extremity lends itself to this type of treatment. The lower extremity is different as it is weight-bearing in character. So profoundly have the excellent results impressed me that I consider this method of treatment a " principle " which should be taught widely. There has been only one case of non-union in my experience, and that was in a simple fracture of the clavicle. With such a record this method of treatment is certainly worthy of consideration, as not only are the results quicker but are better than by other means.

I am glad to say that my old house surgeons and many of my old pupils are at present engaged in carrying out the treatment of fractures on this principle, and so far I have not heard of any of them being disappointed.

I am, Sir, yours faithfully,

Edinburgh, Oct. 13th, 1925. J. W. Dowden.

PROPOSED MEMORIAL TO THE LATE MR. HAMILTON DRUMMOND.

To the Editor of The Lancet.

Sir,—The tragic death of Mr. Hamilton Drummond is so fresh in the minds of the medical profession that it is unnecessary to detail the circumstances of that calamity. He was so well known and so greatly beloved by those in all walks of life that it is felt that some memorial should be promoted. A committee of his colleagues on the staff of the Royal Infirmary, together with some non-medical friends, has been formed for the purpose of carrying out this object. It is proposed that the memorial should be connected with the Newcastle-upon-Tyne Infirmary and the Medical School which he served so faithfully, and in which he was so much interested. The exact form of the memorial must be decided at a later date, and will largely depend upon the amount subscribed. The committee has decided to appeal for subscriptions up to a limit of 5 guineas, but it is hoped that all who cherish his memory will subscribe irrespective of the amount.

The following is a preliminary list of subscribers for amounts totalling £395 14*s.* already received or promised :—

Mr. H. B. Angus, Dr. Arnison, Dr. Armstrong Atkinson, Mr. J. Anderson, Mr. Arkle, Dr. Allison, Dr. Adams.

Mrs. J. L. Boyd, Dr. R. A. Bolam, Dr. V. E. Badcock, Mr. A. H. Burgess, Dr. Beattie, Dr. A. Brumell, Mr. Barclay, Dr. Bishop, Mr. S. Barling, Dr. Edgar Babst.

W. T. Cochrane, Mrs. W. T. Cochrane, Mr. J. Clay, Mr. Arthur Cooke, Colonel Cookson, Dr. J. Charles, Dr. Mabel Campbell.

C. Davey, Mr. Dickie, Dr. W. Davidson.

Mr. H. Evers.

Mr. Ernest Finch.

Dr. Gamlen, H. A. Graves, Sir C. Gordon-Watson, Dr. M. Glasse, Mr. Gilmour.

Dr. W. E. Hume, Dr. Hall, Dr. Hunter, Dr. Hindmarch, Mr. Hodgson.

Mr. Irwin.

Mr. A. M. Johnston.

Miss Kirkhouse.

Sir Alexander Leith, Bart., Mr. J. W. Leech, Dr. R. P. R. Lyle, Dr. Lloyd.

E. Matheson, Mr. A. M. Martin, Dr. Muirhead, Mr. John Morley, Mr. K. W. Monsarratt, Dr. R. E. Moyes, Dr. F. Murray, Dr. S. McDonald, Dr. Mona McNaughton.

Sir George Noble, Bart., Mr. Philip Noble, G. P. Noble, H. W. Noble, P. E. Noble, Dr. Nattrass.

Dr. Ogden, Sir Thomas Oliver.

Mr. F. C. Pybus, Dr. Parkin, Dr. Patterson.

Dr. Ruxton.

T. N. Sample, Mrs. T. N. Sample, Dr. James Smith, Mr. Graham Simpson, Dr. Spence, Dr. Slade, Dr. Wilkie Smith, Dr. A. Smith, Dr. E. D. Smith, Mr. Herbert B. Speke.

J. E. Taylor, Mr. G. Grey Turner, Dr. Thompson.

H. A. Westmacott, Mrs. Westmacott, Mr. Wilson, Mr. R. J. Willan, Mr. J. D. Wardale, Mr. S. S. Whillis, Dr. Weidner, Mr. G. E. Wilkinson, Dr. F. S. Walker, Mr. A. Whitelocke, Mr. Wardill, Dr. Hedley Whyte, Dr. Welsh.

Prof. R. P. Ranken Lyle and Mr. Philip E. Noble have been appointed joint treasurers. Subscriptions may be sent to the former at 11, Osborne-terrace, or to Messrs. Lloyds Bank, Ltd., Grey-street, both in Newcastle-upon-Tyne, or to any of the following : Prof. H. B. Angus, Prof. Thomas Beattie, Sir Alexander Leith, Bart., Mr. A. M. Martin, Mr. Philip E. Noble, Sir Thomas Oliver, Mr. Herbert B. Speke.

I am, Sir, yours faithfully,

G. Grey Turner,
Oct. 16th, 1925. Convenor of Committee.

THE DANGER OF SELF INSULIN INJECTION.

To the Editor of The Lancet.

Sir,—All patients are not as apt as Prof. Pirquet's (The Lancet, Oct. 10th, p. 765). A recent case under the care of Dr. H. Batty Shaw illustrates the risk to patients of self-injection of insulin.

A. B., aged 22, had been receiving 75 units of insulin per diem for eight months. The injections were made by the patient himself at home, some into his upper arm, but most into the upper part of both thighs. According to the patient, a small lump formed at the site of injection, which in some cases discharged, leaving an ulcer. He was admitted to University College Hospital in a semi-comatose condition, with air-hunger, and the urine was found to reduce Fehling's solution. A diagnosis of diabetic coma was made, repeated injections of insulin were given (100 units in all), and rapid recovery ensued. The statement made by the patient showed that the injections were not properly performed ; some of the fluid escaped from the needle and was not introduced into the tissues. There were 15 ulcers, 12 on the right leg and 3 on the left, the largest being 4/5 × 2/5 in. The ulcers reached a certain size and then spread no further. The bases consisted of smooth granulation tissue, pink in colour ; the edges were slightly raised, but the ulcers were shallow. Round some of the ulcers there was considerable thickening, which involved the tissues beneath the skin. In certain parts of the thigh thickened subcutaneous tissue could be palpated, and these had not ulcerated. Over these thickenings some slight reddish discoloration of the skin was observed. There seemed to be no attempt on the part of the skin to grow over the ulcerating areas. The technique of the injection as performed by the patient was as follows : The needle was placed in boiling water and the site of the injection was cleaned with methylated spirit.

No doubt similar cases have occurred and others will continue to occur as the use of insulin becomes more widespread. Some better arrangement is needed to avoid the development in these cases of diabetic coma directly due to faulty technique.

I am, Sir, yours faithfully,

A. C. M. Elman, M.B., B.S. Lond.,
Late House Physician, University College Hospital,
Oct. 15th, 1925. London, W.

Dr. Henry Alfred Alford Nicholls, C.G.M., has been appointed an Unofficial Member of the Executive Council of the Presidency of Dominica.

Medical News.

UNIVERSITY OF OXFORD.—Dr. Richard Stephen Creed, of Trinity, has been elected to a Fellowship in Physiology at New College. Dr. Creed held a Millard Scholarship at Trinity, was subsequently elected to a Senior Demyship of Magdalen College, and has since had various appointments at St. Thomas's Hospital.

UNIVERSITY OF GLASGOW.—The following medical degrees were conferred on Oct. 19th by the Vice-Chancellor, Sir Donald MacAlister :—

M.D.—Grenville W. St. Clair Ramsay (with high commendation) and Alexander M. Macqueen.

M.B., Ch.B.—With honours : Janet S. F. Niven and John V. Thomson. With commendation : Gavin S. Anderson, Elias Bloch, Alexander Dale, Josiah R. Bailey, and Catherine A. Brown. Ordinary degree : William J. Aitken, James W. M. Alexander, William Allison, John Anderson, John G. Anderson, David E. Aspin, William J. C. Auld, William J. Barbour, Arthur D. Briggs, James C. Brown, Douglas N. Buchanan, James H. Burnside, Alexander M. Campbell, Jeanie G. Campbell, John Campbell, John B. Carrigan, John F. Christie, William A. S. Couper, Francis A. Coutts, Alexander W. Cuthbert, John G. Dalgleish, Thomas H. Dalrymple, Jack V. M. Davies, Jean M. Dixon, Matthew K. Dunlop, Maurice Freeman, Mary A. Frew, Sydney M. Galbraith, Annie Gartly, Elena Gill, Douglas W. Gillies, Gordon Gillies, Agnes M. Hamilton, Everard Henderson, Nettie S. Hendry, William Hope, William Hosie, Jeanie M. Howitt, David G. Hunter, Elizabeth F. Hunter, William Hutchison, James Jarvie, David Johnston, Julia P. Johnston, Robert Johnstone, Annie C. Kerr, Charles S. Kerr, James G. Kidd, Isobel C. King, Peter S. Kinloch, Andrew P. Laird, Elizabeth H. Livingston, Mary C. Livingstone, John L. Macaulay, Robert P. J. McBroom, John A. McCluskie, William J. McCulley, JamesMacDonald, James S. Macdonald, Archibald MacEwan, John F. Macfarlane, David G. D. McGregor, George T. MacGregor, Jean N. McGregor, William McIlvenna, James McIntyre, Archibald A. MacKelvie, Helena M. McKnight, Murdo H. Maclaine, Agnes F. H. McLean, William MacLean, Donald Macleod, Susan M. MacMurray, Mona H. Macnie, John S. McTavish, William Mercer, William Murray, Arthur F. Nimmo, John Parker, Margaret F. Paton, William D. Peock, Pauline Podlashuk, Elizabeth M. Rattray, Joseph Ribchester, Christopher G. Rippin, Ruth M. L. Ross, Alfred G. Shanks, Helena M. Shanks, Thomas M. Sharp, Robert K. Shearer, Jean W. Smellie, Vida J. M. Stark, Hugh Stewart, Edith K. Stocker, Frederic Syson, David Thomas, Jean G. Thomson, Hugh A. Walker, Maggie B. Walker, James B. Watson, Henrietta C. Weir, Evelyn A. Weyman, Dorothy F. M. Whiteford, Elizabeth C. Whyte, Alexander F. Wood, Thomas Young, and Tchi-waang Yun.

Janet S. F. Niven gains the Brunton Memorial Prize awarded to the most distinguished graduate in medicine of the year, and Morton A. Foulis gains the West of Scotland R.A.M.C. Memorial Prize awarded to the candidate with the highest aggregate marks in medicine, surgery, and midwifery in the Final Examinations for the degrees of M.B. and Ch.B. held during the year 1925.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful :—

FINAL MEDICAL EXAMINATION.

Part I.—Solomon Behr (passed on high marks), Wilfreda D. C. T. Pigott, Wilfred F. Lane, Richard M. Moore and Gilbert M. Smith (equal), Paul M. Garry, Thomas F. M. Woods, Lenox R. S. MacFarlane, Charles L. Day, Nathaniel Burstein, David M. Carson, George M'Donald, Andrew C. C. Charles, and Joseph A. K. FitzGerald.

In completion.—Kathleen R. Byrne, Evelyn E. Connolly, and Desmond Blewitt.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

Joseph Rego and Amy B. R. A. Perriton.

THE L.C.C. AND IMMUNISATION AGAINST DIPHTHERIA.—In March, 1924, the Public Health and Education Committees of the London County Council were directed to "consider and report whether or not the treatment carried out by the department of health in New York City for rendering children immune from diphtheria should be adopted in the London schools." In their consideration of the subject, the two Committees have had before them a report by the medical officer of the Council, presenting a review of the work which has been carried out in connexion with active immunisation for the control of diphtheria both at home and abroad, and it is understood that the Ministry of Health are conducting inquiries with regard to immunisation of the staffs of fever hospitals, and in connexion with maternity and child welfare work. The L.C.C. Committees have been advised that these lines of investigation should be thoroughly explored before further consideration is given to the question of immunisation of children of school age. The Committees have, therefore, reported to the Council that, in their opinion, it is not advisable at the present time that toxin-antitoxin treatment in connexion with the prevention of diphtheria should be adopted as part of the Council's scheme of medical treatment of school-children.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual dinner of this Society was held on Oct. 16th at the Piccadilly Hotel, Dr. George F. Buchan, President of the Society, being in the chair. A large number of medical officers of health, several of whom had passed the chair, were present, while the guests included Sir Alfred Mond, M.P., Minister of Health in one of Mr. Lloyd George's Cabinets ; Sir H. Kingsley Wood, M.P., Parliamentary Secretary to the Ministry of Health ; Sir Walter Fletcher, Secretary of the Medical Research Council ; Sir StClair Thomson, President of the Royal Society of Medicine ; Sir Arthur Chapman, Chairman of the County Councils Association ; Sir George Newman, Chief Medical Officer to the Ministry of Health ; Sir William Leishman, Director-General, A.M.S. ; Sir Bruce Bruce-Porter ; Colonel F. E. Fremantle, M.P. ; Dr. Alfred Cox, Medical Secretary of the British Medical Association ; and Sir Squire Sprigge, Editor of THE LANCET.

The principal toast, that of "Prosperity to the Society," was proposed by Sir Kingsley Wood, who acknowledged warmly for his department the loyal coöperation of the medical officers of health during the past year. He said that he refused to give way to the new disease of "pessimitis" in respect of health progress, and reminded his hearers, giving dramatic figures for comparison, of the decline which had taken place in the national death-rate of recent years, and the great improvements in the expectation of life and in the infantile mortality-rate, amounting to a revolution in medicine. A similar story of progress could, he said, be told in connexion with the incidence of enteric fever and of tuberculosis. He concluded by alluding to the necessity of a closer linking up of the various health authorities of the country.

Dr. Buchan replied for the Society in a studiously quiet manner with a gratifying story of good work done. He pointed to the progress of public health along most lines of its numerous departments, and made the valuable suggestion that no medical man should proceed to his final degree or diploma until he had ascertained something of the pattern of public health administration at any rate in his own area. But he urged that if workers in public health were to obtain good results local authorities must take a closer interest than at present in the research work necessary to modern preventive medicine, while he enumerated the future objectives of public health endeavour in a succinct series of headings.

The toast of the Guests was proposed by Dr. W. J. Howarth in very generous mood, and was responded to by Sir Alfred Mond in a humorous reply. Protesting against the introduction of a new disease by the Parliamentary Secretary to the Ministry of Health, he said that the duties of the medical officer of health were sufficiently heavy already, comprising, as he conceived them, the equipment of an architect and builder, a land surveyor, an engineer, a medical practitioner, and a chemist, while he himself had had something to do with the new responsibilities in respect of milk. How efficiently those multifarious duties were at present discharged he considered proved by the fact that our national pattern of public health administration had been copied by all advancing civilisations, while no nation as yet had attained to the high level of the pattern. He closed by a reference to the establishment, through the generosity of the Rockefeller Foundation, of a new College of Hygiene in London. Sir Arthur Chapman and Sir StClair Thomson also replied, the latter speaking for the Royal Society of Medicine : "One of the revolutionary bodies passionately admired by Sir Kingsley Wood, a Conservative Minister, although their house at 1, Wimpole-street had not yet been raided. But the medical revolution raised by medical men did not, as one poet put it, bring red ruin and the breaking up of laws, but as another poet put it, it moved towards drinking in larger life from fuller air." Sir Kingsley Wood, he added, had so eloquently pointed out the gain to the country in health and wealth brought about by the activities of the M.O.H.'s that no doubt a grateful country and a generous Government would recognise the situation by steady increases of salary. Due acknowledgment was made of the services of Mr. G. S. Elliston, executive secretary of the Society and editor of the *Medical Officer*.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Oct. 26th, at 5.30 P.M., Dr. Marcus Paterson will give the second lecture for the Fellowship of Medicine on the Treatment of Pulmonary Tuberculosis at the Medical Society of London, 11, Chandos-street, W. All members of the medical profession are welcome. During the month of November the London Lock Hospital will hold a comprehensive course in venereal disease. At the Chelsea Hospital for Women there will be a three weeks' course in Gynæcology from Nov. 2nd to the 21st From Nov. 3rd to the 28th Dr. Porter Phillips and Dr.

Thomas Beaton will give twice weekly lecture-demonstrations on Psychological Medicine at the Bethlem Royal Hospital. There will be a course in Diseases of the Chest, Heart, and Lungs at the Victoria Park Hospital from Nov. 9th to the 21st. The Royal Waterloo Hospital will give a course in Medicine, Surgery, and Gynæcology from Nov. 23rd to Dec. 12th, embracing all the departments pertaining to diseases of women and children. A late afternoon course (4.30 to 6 o'clock) will be held at the London Temperance Hospital from Nov. 23rd to Dec. 4th for the benefit of the general practitioner. Application for copies of each syllabus and for the general programme should be made to the secretary at 1, Wimpole-street, London, W. 1.

University of Bristol: Association of Alumni (London Branch).—The annual dinner will be held on Friday, Nov. 6th, at 7.30 for 7.45, at Pagani's Restaurant, 42–48, Great Portland-street, London, W. Viscount Haldane will preside and Prof. Lloyd Morgan will be the guest of the evening. Tickets may be obtained from the hon. secretary at Holloway Sanatorium, Virginia Water.

Vienna: Post-graduate Course.—The Vienna Medical Faculty has now prepared the syllabus of its nineteenth post-graduate course on syphilology and dermatology with special reference to treatment, for native and foreign medical practitioners, which will be held from Nov. 23rd to Dec. 6th. Copies of the syllabus and further information may be obtained from the Dean, Prof. Richard Wasicky, Ring des 12 November, Universität, Vienna.

Royal College of Physicians of Ireland.—The annual meeting of the College was held on the morrow of St. Luke's Day, when the following officers were elected. President: Dr. T. H. Wilson. Censors: Drs. W. A. Winter, G. FitzGibbon, G. E. Nesbitt, R. J. Rowlette. Treasurer: Dr. H. T. Bewley. Registrar: Dr. T. P. C. Kirkpatrick. Dr. Wilson, the new President, has been a Fellow since 1898, and has been King's Professor of Midwifery in the School of Physic since 1911.

Two Vacant Chairs of Medicine.—Dr. John Mallet Purser has resigned the Chair of the Regius Professor of Physics in Dublin University, to which he was appointed in 1917 after the death of Dr. James Little. Dr. Purser had been King's Professor of the Institutes of Medicine in the School of Physic from 1874 to 1902. He has recently been in ill-health. The vacancy will be filled in December. Dr. Joseph O'Carroll has resigned the Chair of Medicine in University College, Dublin, National University of Ireland, to which he was appointed in 1912 on the death of Sir Christopher Nixon.

Welsh School of Medicine.—A special meeting of the Court of the University of Wales was held on Oct. 16th at Llandrindod Wells to consider the following resolution: "The University Court, having considered the present position of the Welsh National School of Medicine in the University, and having taken account of the correspondence between His Majesty's Privy Council, the University Council, and the Council of the University College of South Wales and Monmouthshire in regard to the position of the school, is of the opinion that, with a view to providing for the full development of the School of Medicine as a national centre for medical education and research in Wales, the best interests of the school will be served by constituting it an independent school in the University. The University Court, therefore, hereby resolves, on the recommendation of the University Council, to submit a humble petition to His Majesty in Council for a charter incorporating the school as an independent school of the University of Wales." After full discussion, in which the Principal of Cardiff College, Sir Isambard Owen, and Prof. Joseph Jones, among others, took part, the motion was put and carried by 71 votes to 41. It was agreed to refer the drafting of the scheme to the University Court in consultation with the University Council of Cardiff College.

Manchester and Salford Medical Charities.—At the annual meeting held on Oct. 15th of the Hospital Sunday Fund it was stated that the income for the year, £26,181, represented an increase of £19,000 on the previous year's figures, due principally to the inclusion in the accounts for the first time of the Alexandra Day Fund, amounting to over £3000, and to an increase of nearly £6000 in the ordinary income. Particular praise is due to the students of the University of Manchester, who have increased the yield of their "rag" on Shrove Tuesday to over £6000, being £3000 in excess of the corresponding contribution the previous year. The one disappointment was the fall of £1000 in the amount collected in the churches on Hospital Sunday, probably due to the execrable weather on that day. Amongst the various local medical institutions £23,650 was distributed, being £10,000 more than was distributed last year. In spite of this satisfactory result the committee of management are faced with a serious difficulty owing to the fact that the cost of maintaining patients from the outside districts was considerably more than the amounts contributed by these districts. During the year 40,520 cases were treated from outside districts at a cost of £103,776, while the amount contributed was only £57,605. A contribution of one penny per week by every employed person in the district would realise £50,000 in each year.

Manchester Medical School.—The annual dinner of the school will be held in the Grand Hotel, Manchester, on Thursday, Nov. 19th, Mr. C. Roberts in the chair.

Nottingham Medico-Chirurgical Society.—At the first meeting of the session on Oct. 30th Sir StClair Thomson will give an address on Dysphagia and Some Diseases of the Œsophagus. Mr. H. Bell Tawse will be in the chair.

Hospital of St. John and St. Elizabeth.—The Tetley Theatre, the Winifred Bertha de la Chare Isolation Ward, and the X ray department of this hospital, at 40, Grove End-road, London, N.W. will be formally opened on Thursday, Oct. 29th, at 3.30 p.m.

Chester Maternity Hospital.—The Marchioness of Cambridge recently opened a new maternity hospital provided by a combined effort of the Chester Benevolent Institution, founded in 1789, and the District Nurses' Association, both of which are now amalgamated with the hospital. The first baby born in the institution was presented with a silver cup.

Hospital Saving Association.—The contributors to this association now number over 180,000. From the beginning, in 1922, about £100,000 has been received, £63,000 of which has been paid to coöperating hospitals. Refunds amounting to £11,356 have been paid to contributors admitted to non-coöperating hospitals, and a further £16,000 has been refunded to contributors in respect of extra hospital benefits.

King's College Hospital Debt.—Having failed to repay completely the debt to the bank, the committee of management have decided to sell all their war loan on general account, which has appreciated in value. This will leave a debt of only about £5000 which it is hoped to clear by contributions without the necessity of selling the remaining securities, the value of which has decreased since the hospital became possessed of them.

Medico-Legal Society.—A meeting of this society will be held to-day (Friday), at 8.30 p.m., at 11, Chandos-street, Cavendish-square, W., when Dr. Nathan Raw and Mr. D. Harvey J. Hartley, the society's representatives at the International Prison Congress held in August, 1925, will present their report, which will form the basis of the subsequent discussion. Lord Justice Atkin will be in the chair.

We have received a decorative booklet on "Artificial Sunlight" from Watson and Sons (Electro-Medical), Ltd., of Parker-street, Kingsway, London, W.C. The cover and general production are intended to be in keeping with the subject and do not lack brightness. Messrs. Watson conclude that "it is impossible to cover all the exigencies of phototherapy with one type of equipment," and give an excellent account of the lamps which they supply.

Chelsea Clinical Society.—The annual dinner of this society was held in the Café Royal, Regent-street, on Oct. 20th, when over 60 members and their guests assembled. The President, Dr. Seymour Price, was in the chair. The toast of the Society was proposed by Sir Holburt J. Waring, President of the Medical Society of London, who spoke of the value of medical societies in, amongst other things, training members to take part in municipal and civic affairs. There are, he said, far too few members of the medical profession at present in the House of Commons. Dr. Seymour Price, in reply, mentioned two innovations in the society's programme which would come into effect during the winter, first that the meetings would be held in the board room and not in the smaller club room, as formerly, of St. George's Hospital, and second that two dinner meetings would take place in the Florence Restaurant, Wardour-street, in the course of the session. Mr. Ivor Back, in a speech sparkling with amusing anecdotes, proposed the Visitors, coupled with the names of Sir Holburt Waring; Dr. Howard Humphris, President of the Hunterian Society; Dr. H. W. Armstead, President of the West London Medico-Chirurgical Society; and Dr. V. Dickinson, Master of the Society of Apothecaries. Dr. Dickinson replied on behalf of the guests. The President was then proposed by Dr. K. E. Eckenstein, the treasurer of the society; Dr. Seymour Price defended himself satisfactorily, and paid a tribute to the work of the secretary, Mr. Ralph Thompson, who dutifully urged greater attendance at the society's meetings, tempering his reproof with humour.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Oct. 26th.

ODONTOLOGY: at 8 P.M.

Presidential Address:

Mr. J. Lewin Payne: The Origin and Growth of the Odontological Society.

Paper:

Mr. A. T. Pitts and Mr. J. Howard Mummery: A Melanotic Epithelial Odontome in a Child.

Tuesday, Oct. 27th.

MEDICINE: at 5.30 P.M.

Clinical Meeting at the Middlesex Hospital, W.

Tea will be served at 5 P.M.

SOCIAL EVENING: at 8.30 P.M.

At 8.30 P.M. Fellows and their friends will be received by the President, Sir StClair Thomson.

At 9.30 P.M. the President will give a short address on Shakespeare as a Guide in the Art and Practice of Medicine.

There will be an interesting exhibition, arranged by Mr. C. J. S. Thompson, of the Wellcome Historical Medical Museum, to illustrate the subject of medicine in the Elizabethan period and the references to medicine in the plays of Shakespeare.

Wednesday, Oct. 28th.

COMPARATIVE MEDICINE: at 5 P.M.

Presidential Address by

Mr. Frederick T. G. Hobday.

Paper:

Dr. W. H. Andrews: Some Recent Advances in Our Knowledge of Plant Poisoning.

A discussion will follow, to be opened by Prof. A. J. Clark.

PSYCHIATRY: at 8.30 P.M.

Joint Meeting with the British Psychological Society (Medical Section).

Discussion on

The Early Treatment of Mental Disorders, to be opened by Sir Maurice Craig and Dr. William Brown.

Thursday, Oct. 29th.

UROLOGY: at 8.30 P.M.

Presidential Address:

Mr. R. H. Jocelyn Swan: Some Reflections upon Villous-covered Tumours of the Bladder.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

Monday, Oct. 26th.—8.30 P.M., Clinical Evening: Exhibition of Cases and Skiagrams.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Oct. 26th, to Saturday, Oct. 31st.—Fellowship of Medicine lecture, Medical Society, 11, Chandos-street. Mon., 5.30, Dr. Marcus Paterson: The Treatment of Pulmonary Tuberculosis.—London School of Hygiene and Tropical Medicine, Endsleigh-gardens. Tues. and Thurs., Clinical demonstration by Dr. G. C. Low and Dr. Manson-Bahr.—Royal Northern Hospital, Holloway-road, N. Intensive Course in Medicine, Surgery, and the Special Departments.—St. John's Hospital, Leicester-square. Daily demonstrations in the Out-patient Department. Bi-weekly lectures. Tues., Dr. Barber: Immunity, Anaphylaxis. Thurs., Dr. Griffith: Principles of Treatment. General. Practical Pathological Demonstrations.—St. Peter's Hospital, Henrietta-street, W.C., Special Course in Urology. Clinical work every afternoon and lecture.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Thursday, Oct. 29th.—3 P.M., Demonstration: Mr. W. E. Tanner: Selected Surgical Cases. 4.30 P.M., Lecture: Mr. H. W. Carson: The Differential Diagnosis of Conditions Simulating Appendicitis.

Daily: Clinics and demonstration in the Wards and various Out-patient Departments, Operations, &c.

UNIVERSITY COLLEGE, London.

Monday, Oct. 26th.—5 P.M., Mr. R. J. Lythgoe: The Physiology of Hearing and Vision. Fifth lecture.

Wednesday.—5 P.M., Sixth lecture.

ST. JOHN'S HOSPITAL, Leicester-square, W.C.

Tuesday, Oct. 27th.—5 P.M., Dr. H. W. Barber: Immunity. Anaphylaxis.

Thursday.—5 P.M., Dr. W. Griffith: Principles of Treatment. General.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: October-November, 1925.

Clinical Lectures and Demonstrations.

Monday, Oct. 26th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., The Psychical Aura in Epilepsy: Dr. Kinnier Wilson.

Tuesday, Oct. 27th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Compression Paraplegia from a Surgical Standpoint: Mr. Armour.

Thursday, Oct. 29th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Ocular Palsies: Dr. Gordon Holmes.

Friday, Oct. 30th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Demonstration of Swedish Remedial Exercises (in Exercise Room): Mr. Elmquist.

The fee for the Course, including Pathology Lectures, is £5 5*s*. For those who hold Perpetual Tickets the fee is £3 3*s*.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Thursday, Oct. 29th.—12 noon, Periaxial Degeneration: Dr. J. G. Greenfield.

Course of Lectures and Demonstrations on the Anatomy and Physiology of the Nervous System.

Monday, Oct. 26th.—12 noon, The Brain Stem and Cerebellum: Dr. J. L. Birley.

Dr. H. J. MacBride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards of 10 A.M. on Tuesdays and Fridays, commencing Oct. 20th. The fee for this Course will be £2 2*s*.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Oct. 27th.—4.15 P.M., Mr. W. H. Hey: Prognosis in Abdominal Disease.

Friday.—4.15 P.M., Prof. E. D. Telford: The Diagnosis of Chronic Arthritis in Children.

ANCOATS HOSPITAL POST-GRADUATE LECTURES.

Thursday, Oct. 29th.—4.15 P.M., Mr. E. E Hughes: The Significance of Urinary Symptoms.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Oct. 28th.—4 P.M., Dr. J. D. Rolleston: Prevention and Arrest of Diphtheria.

PEOPLE'S LEAGUE OF HEALTH, Fyvie Hall, Regent-street Polytechnic.

Friday, Oct. 30th.—6 P.M., Prof. B. Collingwood: Sewage Systems of the Human Body.

Appointments.

Brentnall, C. P., M.B., Ch.B. Liverp., has been appointed Honorary Assistant Surgeon to the St. Mary's Hospitals, Manchester, and Honorary Assistant Gynæcological Surgeon to the Northern Hospital, Manchester.

Butt, E. S., L.D.S., School Dentist for Cheshire.

Cook, F., M.B., B.S. Lond., F.R.C.S. Eng., Surgeon to Out-patients, Chelsea Hospital for Women.

Darwent, C. T., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., Assistant Medical Officer to the Dundee Education Authority.

Menzies, F. N. Kay, M.B., Ch.B., F.R.C.P. Edin., D.P.H., Medical Officer of Health and School Medical Officer to the London County Council.

Thomas, H. A., M.B., Ch.B. Liverp., Assistant Medical Officer of Health and School Medical Officer for Denbighshire.

Royal Infirmary, Liverpool: Nuttall, H. C. W., F.R.C.S. Eng., F.R.C.S. Edin., Honorary Assistant Surgeon; Wilson, J. St.G., Ch.M., F.R.C.S. Eng., Honorary Assistant Gynæcological and Obstetrical Surgeon; Herd, S. B., M.D., Ch.B. Liverp., Additional Honorary Assistant Gynæcological and Obstetrical Surgeon.

Salford Royal Hospital: Bird, Elizabeth, M.B., Ch.B. Glasg., Radiologist; Earl, C. J. C., M.R.C.P., L.R.C.S. Irel., Medical Registrar; and Brough, A. Lothian, M.B., Ch.B. Glasg., District Medical Officer.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Asst. S. to Ear, Nose, and Throat Dept.

Anamallai Medical Assoc., S. India.—M.O.

Bengal and North-Western Railway Co., Ltd.—Sen. and Jun. M.O.'s. Rs.1200 and Rs.750 per mensem respectively.

Bolton County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Brighton, New Sussex Hospital for Women and Children.—Hon. Radiologist.

Cardiff, Welsh National School of Medicine.—Asst. to Surg. Unit. £350.

Charing Cross Hospital Medical School.—Lectureship in Hygiene.

Chelsea Hospital for Women.—Anæsthetist. £21.

City of London Hospital for Diseases of the Heart, Victoria Park, E.—H.P. At rate of £100.

Colchester, Severalls Mental Hospital.—Second Asst. M.O. £630.

Crichton Royal Mental Hospital, Dumfries.—Clin. Pathologist. £400.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. At rate of £175.

Essex Administration County.—Asst. Tuberc. O. £600.

Greenwich, Dreadnought Hospital.—S. in charge of Out-patients.

Grove Park Hospital, Lee, S.E.—Med. Supt. £770.

Hayward's Heath Hospital.—Hon. Ophth. S.

Hospital for Sick Children, Great Ormond-street, W.C.—Med. Reg. and Pathologist. £300.

Infectious Hospitals Service, Metropolitan Asylums Board.—Jun. Asst. M.O. £500.

Leicester Royal Infirmary.—H.S. and H.P. At rate of £125 and £120 respectively.

Liverpool Hospital for Consumption and Diseases of Chest, Mount Pleasant.—Hon. Asst. P.

Manchester City Education Committee.—Asst. Sch. M.O. £600.

Middlesex County Council.—Asst. M.O. £600.

Northampton General Hospital.—Hon. Asst. S.

North Middlesex Hospital, Edmonton, N.—Asst. S. £500.

Oxford, Warneford Mental Hospital.—Asst. M.O. £250.

Perthshire Joint Medical Service Scheme.—First Asst. M.O. £600.

Plaistow Fever Hospital, E.—Second Asst. M.O. At rate of £200.

Poplar Hospital for Accidents, East India Dock-road, E.—Second Res. Surg. O. £175.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P., First H.S., Second H.S., and Asst. Cas. O.

St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. and Asst. Res. M.O. At rate of £175 and £130 respectively. Also Hon. Dental S.

St. Pancras Dispensary, 39, Oakley-sq., N.W.—Res. M.O. £225.

Stoke-on-Trent, North Staffs, Royal Infirmary.—H.S. £150. Also H.P. £125.

Stourbridge, Worcestershire, Corbett Hospital.—H.S. £150.

Wakefield, City of.—Deputy M.O.H. £600.

Wallasey, Victoria Central Hospital.—Jun. H.S. £100.

Westminster Hospital, S.W.—M.O. Two Asst. M.O.'s to X Ray Dept. Also Asst. Path.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment for a Certifying Factory Surgeon at Friockheim, Forfarshire,

Births, Marriages, and Deaths.

BIRTHS.

Cossham.—On Oct. 14th, at "St. Aldwyns," Cirencester, Glos., the wife of D. G. Cossham, M.B., of a daughter.

Farmer.—On Oct. 12th, the wife of F. J. Farmer, L.D.S. R.C.S., of a son.

Welch.—On Oct. 17th, at West Norwood, the wife of Cyril H. Welch, M.D., of a daughter.

MARRIAGES.

Anderson—Wharton.—On Oct. 9th, at St. Nicholas's Church, Great Yarmouth, Archibald Stirling Kennedy Anderson, D.S.O., M.C., M.A., M.B., Ch.B., D.P.H., to Joyce, elder daughter of Mr. and Mrs. W. S. Wharton, of Great Yarmouth.

Lauder—Thompson.—On Oct. 3rd, at St. James's, Sussex-gardens, Harold Victor Robert Thomas Lauder, M.R.C.S., L.R.C.P., to Phyllis Anna Lynn, daughter of the late Alfred Lynn Thompson and Mrs. Lynn Thompson, of Westbourne-street, Hyde Park, W.

DEATHS.

Austin.—On Oct. 12th, at Fernleigh, Lingfield, Sydney Charles Austin, M.R.C.S., aged 81.

Goodale.—On Oct. 15th, at Little Bowyer, Wrotham, Kent, Henry Goodale, M.R.C.S.

Haggard.—On Oct. 18th, at St. Bartholomew's Hospital, Thomas Barker Amyand Haggard, late Capt. R.A.M.C., B.A., M.R.C.S., L.R.C.P., aged 50.

Hinde.—On Oct. 20th, at Mundesley, Eric Clark Hinde, M.B., B.S. Lond., aged 30.

Kellett.—Alfred Featherstone Kellett, M.B., B.S., B.A., St. John's College, Cambridge, Associate of Birmingham University; for 33 years practising at Lewisham, S.E., aged 59.

Orrin.—On Oct. 18th, at "Ferndale," Halstead, Essex, Beth, the wife of Herbert Charles Orrin, O.B.E., F.R.C.S., Surgeon, Ministry of Pensions Hospital, Newcastle-on-Tyne.

Pritchard.—On Oct. 16th, at St. Teresa, Chesham Bois, Bucks, Urban Pritchard, M.D., F.R.C.S., in his 81st year.

Rowland.—On Oct. 18th, at Albert-mansions, Battersea Park, John William Rowland, C.M.G., M.B., C.M.

Serpell.—On Oct. 11th, at a nursing home in Plymouth, after operation, Hugh Hamilton Serpell, M.R.C.S., L.R.C.P., late Lieut.-Colonel R.A.M.C., of Polyphant House, Lewannick, Cornwall, aged 48.

Whitsed.—On Oct. 14th, suddenly, at "Bukloh," Tilehurst, Reading, James Longland Whitsed, M.R.C.S.E., L.R.C.P., aged 74 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE EQUABLE COOLING POWER OF ALPINE HEALTH RESORTS.

By Leonard Hill, M.B.Lond., F.R.S.,
DIRECTOR OF THE DEPARTMENT OF APPLIED PHYSIOLOGY, MEDICAL RESEARCH COUNCIL;
AND
Bernard Hudson, M.D. Camb., M.R.C.P. Lond.,
SWISS FEDERAL DIPLOMA; PHYSICIAN TO VICTORIA SANATORIUM, DAVOS-PLATZ, SWITZERLAND.

Among many other things of interest, the recent Climatological Congress at Davos brought out the fact that one of the chief points about the Alpine climate is the absence of high wind and the equable cooling power of the air, as measured by the kata-thermometer. Dr. Dorno, the distinguished meteorologist at Davos, has made observations illustrating the latter fact, and Dr. Paul Gotz has recently communicated to us figures which show that this equable cooling power holds good also for Arosa. On a balcony with south aspect, the average dry kata cooling power for the different months of the year varied there only 7½ to 15. In the open at Davos the variation is from 10 to 24. The Davos valley, running north to south, is peculiarly sheltered, and the perfectly straight, slender growth of the pines illustrates the fact that neither gales nor stunting winds blow there. The variation of dry kata cooling power is very great in the changeable and windy climate of Great Britain, in the open from 7 to 50 or even 60, with a monthly average varying from 21–40, but confined city courts are sheltered, and offer near the ground equable cooling power, as is shown by the anemometer and temperature records taken in a court in Camden-square, from which dry kata thermometer cooling powers of 5½ to 10 were calculated for the year. In comparison may also be cited the monthly average cooling powers calculated for Sierra Leone 7½–12, Kimberley, S.A., 13–25, and Quebec 18–63.

In the Alpine health resorts the winter sunshine and ultra-violet rays have high values in contrast to the city court-yard. The acetone blue gauge shows that the ultra-violet radiation in Kingsway is about one-third of that in clean country air. In the Alps the hours of winter sunshine equal those in summer on the south coast. Moreover, the physiological saturation deficit is higher in the Alps—that is, the difference between the weight of water vapour in the inspired air and that in the expired air which has been saturated and warmed in the lungs. The phthisical patient gets advantage not only from the sunshine and ultra-violet radiation, but also from the high evaporative power of the air acting upon the lungs and promoting the passage of blood, lymph, and secretion through the respiratory membrane. The attenuated cool air, by promoting deeper breathing, increases these effects. He also gets advantage from absence of warm, close days and cold wind and from the equable cooling power. The cooling power in the Alps is just within those limits which are felt to be fresh and pleasant, particularly when there is available a source of radiant energy such as is given by sun- and sky-shine. The patient is pleasantly cooled by the winter cooling power of the Alpine air, and his resting metabolism is kept up at a high level, his general well-being and his appetite thus being improved. The increase of resting metabolism found by one of us (L. H.) and Argyll Campbell in tuberculous patients submitted to open-air treatment has been confirmed recently by observations made by Dr. Vogel-Eysern at Davos. The patient in the Alps is never overheated whilst in the cool, shady air with high drying power, and great care must be taken that he does not become overheated in enclosed balconies or sun-boxes by direct exposure to hot sun and insufficient circulation of cooling air around him. He can get all the ultra-violet rays he needs from sky-shine and from the direct sun of the cool early morning hours. The absence of high wind prevents discomfort arising from too high a cooling power, and allows light clothing to be worn and does not make exercise difficult, for the patient is not tempted to walk too far with the wind behind him and then have to struggle back against it, arriving home in a state of fatigue, having derived harm instead of benefit from his exercise. Also, owing to the clear, dry, windless air, the patient is enabled to sit down and rest in comfort when necessary, whether in winter or in summer. These advantages, together with the beautiful and exhilarating scenery and the pageant of winter sports to watch, are offered by the Alps. We can, in our cities, make good the absence of sunshine by the use of arc lamps, a great help, but it is not possible to make good all the other things which appeal particularly to young adults.

While benefit may thus be derived by patients suffering from pulmonary tuberculosis in the Swiss Alps, it should be mentioned that only those cases should be sent who have sufficient resistance and power of response to react in the right way to the altered conditions which obtain at a height of 5000 feet or thereabouts. It is no use sending out to the mountains cases in the last stages with active spreading disease, emaciated, worn out, and with no reactive power. It is early cases and even those in later stages, if with sufficient resisting power, which make satisfactory and stable recoveries in the Alps if sufficient time is given. An average sojourn certainly should not be for less than six months, and it is better still to devote one year and even longer, with periods of change of environment when necessary, if permanent results are to be obtained. The danger of catarrhal infections during periods of change of environment must be borne in mind. The patient who returns from the Alpine open-air treatment to crowded trains and cities is susceptible to catarrhal infections against which the citizen is more or less vaccinated by frequent small doses.

KARLSBAD MEDICAL WEEK.

SEVEN years ago Karlsbad instituted an international medical week, consisting of lectures and demonstrations with special reference to the famous Czecho-Slovakian baths. The seventh of these short courses was held last month and was attended by a large medical public from many countries. Prof. Otfried Müller, of Tübingen, described the Müller-Weiss method of examining the capillaries by micro-photography. Though the capillaries are regulated and controlled by the central nervous system, they cannot be considered a "peripheral heart." Certain forms of neurosis caused irregularity in the action of these vessels, and he spoke of this phenomenon in connexion with gastric ulcer, various forms of catarrh, neurotic muscle pains, and high blood pressure in the absence of kidney disease. Dr. Alfred Gigon, of Basle, set forth the present position of our knowledge of metabolism, and described the blood changes observed after courses of Karlsbad waters. Prof. von Hösslin, of Berlin, showed that in a dying patient when the pulse and the heart sounds were imperceptible the electrocardiogram gave evidence that the heart continued to function for some considerable time. Prof. Sellheim, of Halle, dealt with the improvement of methods of blood examination in connexion with gynæcology, and emphasised the advantages of the so-called "Lüttge-Mertz-Berg organic extract serum reaction" over the Abderhalden reaction in the early diagnosis of pregnancy. A reaction is obtained with the new method within half an hour. This reaction can also be used, he claimed, to determine the sex of the fœtus. Dr. Josefson, of Stockholm, discussed the connexion between personality and the organs of internal secretion, showing that there was a possibility of moulding the personality at an early stage by adjustment of the endocrine system. Dr. Balin, of Budapest, gave an interesting lecture on auto-digestion and the formation of fatty acid in the tissues of a patient with gastric ulcer. His researches had shown that the hydrogen-ion concentration in such patients' blood was high. The administration of alkalies caused no increase of fatty acid in the urine; the tissues retain the alkali. Prof. Mühlens, of Hamburg, and Prof. R. Kraus, of Vienna, discussed recent progress in the treatment and prophylaxis of tropical diseases, with special reference to South America. It is of interest to note that "Bayer 205" is now called "Germanin." Dr. Tannhauser, of Heidelberg, discussed the relations of obesity to the endocrine organs, and classified several types of that condition. Prof. di Gaspero, of Graz, dealt with the biological functions of the skin, and the particular effects of hydro-, thermo-, and balneo-therapy on the organism, acting through the skin as a medium. The course was organised by Dr. Edgar Ganz, of Karlsbad, and proved pleasant and profitable to all who took part.

LONGEVITY OF THE LEARNED.

To the Editor of THE LANCET.

SIR,—The annotation in THE LANCET of Oct. 10th which deals with literary death-beds might at first sight lead one to suppose that men of letters during the nineteenth century were mostly short-lived. Yet there were notable exceptions to what was probably not meant to be a generalisation. Mr. Stewart Ellis, author of "Mainly Victorian," in a letter to the present writer, says amusingly: "I rather pride myself upon the closing scenes of my subjects' lives," but he draws no macabre conclusions therefrom.

Viewed as a whole, men of letters and the learned generally have often reached great ages. In his well-known book, invaluable up to its date, "Remarks on the Influence of Mental Cultivation and Mental Excitement upon Health," Dr. Amariah Brigham, of Boston, Mass., appends to his essay a table containing over 280 names of celebrities in all ages and the years of their earthly pilgrimage. Some of the centenarian records included in the list are perhaps fabulous. Thus the list is headed by Hippocrates, father of medicine, who, one tradition asserted, died at the prodigious age of 109; more modest estimates of his age are 100 and 80 respectively. Gorgias, the sophist, is said to have reached 107 years. Fontenelle, the man of universal science, was a centenarian, as also were Saadi, the Persian poet, and Herodian, the historian of the Roman emperors. Zeno, the stoic, Simonides, the poet and philosopher, and Isocrates, the orator, were said to be 98 when they died, and tradition asserts that the first named had bitten out his tongue and had spat it in the face of a tyrant many years previously. Among the nonagenarians numbers increase. They are headed traditionally by Sophocles, who was glad in his day to escape from the importunities of Eros, and they include Hobbes, of "Leviathan" fame, and Sir Christopher Wren. Octogenarian men of science or learning are numerous in Dr. Brigham's category, and among them we find Harvey, Roscoe, Kant, Arthur Young, Mead, and Buffon. Dr. Brigham collected his statistics carefully, but did not bring his record beyond 1832, the year of the first publication of his book. Hence the list would be greatly extended by including nineteenth century names such as Darwin, Wallace, Richard Owen, and a host of others. The expectation of life is, of course, far greater now than in the 'thirties of last century. "England is superior in salubrity to any other country in Europe. The average mortality throughout the whole of England and Wales has been, of late years, about 1 in 60 . . . In London the annual mortality in the middle of the last [eighteenth] century was 1 in 20." Thus wrote Dr. Brigham in 1832, and he quotes Dr. Bisset Hawkins, author of "Elements of Medical Statistics" (1829), who notes that in Geneva good mortuary tables have been preserved since 1560, and that the probability of life there during the seventeenth century was no higher than 11½ years.

Writing as an American, Brigham envies England its health and sanity. He is of opinion that men of letters shorten their lives by neglecting their digestions, but he differs from his contemporaries in attributing dyspepsia mainly to "irritation of the brain," the diagnosis made, as you recall, in the case of Frank Smedley. This irritation, thinks Brigham, is only rarely due to disease. More often it is simply the result of mental tension, which can be relieved by a proper attention to exercise and general health. He notes incidentally that American women of the easy classes are lamentably feeble owing to their sedentary habits, and he urges on the lettered of either sex the necessity for more physical activity.

Athletic exercises, undertaken for pleasure or for health reasons, were neglected in Brigham's day all over the world, and children's brains were crammed, à la Paul Dombey, at the expense of their bodies. Men of letters everywhere were, like the American women, home-staying people, and they suffered from having been often treated as mental prodigies during their early education.

I am, Sir, yours faithfully,

Oct. 12th, 1925. BIBLIOGRAPHER.

THE "EUPHOROS" SELF-ADJUSTING ARM-SLING.

To the Editor of THE LANCET.

SIR,—Far more important than the manner of supporting the arm-sling seems to me the correct way of fixing the sling itself. Very often one sees the arm fixed in the wrong way, as the illustration of the "Euphoros" self-adjusting arm-sling (THE LANCET, Oct. 10th, p. 790) shows. To secure immobility of the arm, the outward part of the sling must be put over the sound shoulder. Only then will the arm be immobilised, as a simple try will prove.

I am, Sir, yours faithfully,

E. C. VAN LEERSUM.

Nederlandsch Instituut Voor Volksvoeding,
Amsterdam, Oct. 16th, 1925.

APOPLEXY OF THE SOFT PALATE.

To the Editor of THE LANCET.

SIR,—I have recently had a case similar to those described in THE LANCET of Oct. 3rd (p. 734). In September, 1924, I saw a lady who was very much alarmed in consequence of a hæmorrhage which she thought came from the lung. Nothing to account for the bleeding could be found after careful examination of the chest; on inspecting the fauces, however, small capillary cavities could be seen, and the patient was satisfied when told the hæmorrhage proceeded from one of these which had given way. In August of this year, when in London, she had a similar attack, when she consulted Dr. F. G. Crookshank, who found the same condition existing and reassured her.

I am, Sir, yours faithfully,

Ilkley, Oct. 16th, 1925. W. R. BATES.

WE are informed that the Schering specialties (Atophan, Veramon, &c.) are now distributed by the firm of Schering, Limited, 3, Lloyd's-avenue, London, E.C. 3, to whom application for literature and samples should be made.

Cameron Lectures

Delivered at the University of Edinburgh on Oct. 19th, Oct. 20th, and Oct. 22nd, 1925,

By HARVEY CUSHING, C.B., F.R.C.S. Eng.,
PROFESSOR OF SURGERY IN HARVARD UNIVERSITY.

LECTURE II.*—THE PITUITARY GLAND AS NOW KNOWN.

> " In those creatures that have the *glandula pituitaria* large, (as in Calves, for instance) the two Carotid Arteries meeting about the *sella* of the wedge-like bone presently divide themselves into small twigs, which being interwoven . . . . make on each side a notable *plexus*, called *Rete mirabile* . . . . So that in these creatures that gland seems to be of the same use to the *Rete mirabile*, as the *glandula pinealis* is to the *plexus choroides*, viz., to separate a serous matter from the Arterial Blood. But in Man, (according to the best Anatomists) this *Rete* is wholly wanting; so that . . . . the *glandula pituitare* is of less use in him, than in other creatures that have the *Rete*."—*Thomas Gibson's "Anatomy" (1688).*

The subject before us, in view of the time-honoured association of the pituitary body and the cerebro-spinal fluid pathways, is not so far removed from that of the preceding lecture as might be supposed. But there is still so much about the gland that remains unknown we cannot afford to smile at those who once thought that it served as a strainer for the sedimented waste products of the brain which passed out by the infundibulum as pituita or slime into the nose. This Galenic conception, indeed, persisted for 15 centuries, and as late as 1631, in his " Integrum Morborum," Robert Flood explained the ætiology of coryza on the principle of the siphon action between the ventricles and the nose. Could he have known that the hypophysis is present in all vertebrates and that in the low order of amphioxus a canal lined by ciliated epithelium affords a communication between the buccal and cerebral cavities, he would have had something more than tradition with which to substantiate his beliefs.

But Schneider (he of the membrane), in his " Liber de Osse Cribriformi " (1655), denied the existence of any demonstrable communications; nor could either Willis or Richard Lower or Vieussens find any by the experimental methods at their command. And yet how could a spontaneous cerebro-spinal rhinorrhœa, of which these learned men most certainly have had knowledge, have been accounted for on any other basis? Even Magendie leaves one with the impression that the hypophysis may represent a sort of lymph gland interposed in the fluid pathway.

Truth assuredly lies at the bottom of a well; and that out of these gropings in the dark, the pituitary body, in the past decade or two, should have come to occupy a position in medicine out of all proportion to its size is the more remarkable. Of this I need not remind the members of a school whose professor of physiology not only was a pioneer contributor to our knowledge of its functions, but who has inspired many of his pupils to the making of further discoveries. Indeed, if I am not mistaken, it was he who in his admirable Lane Lectures in 1913 actually baptised the " Endocrines " of which we hear so much to-day. . . .

During the first decade of the century great confusion prevailed in regard to the disorders of the gland. To be sure, acromegaly and gigantism were recognised as clinical entities known to be associated with hypophysial tumefactions, but Pechkranz (1899), Fröhlich (1901), Axenfeld (1903), Müller (1905), Brissaud (1907), and probably a good many others, ophthalmologists and gynæcologists in particular, were calling attention to the existence of tumours of the gland or its neighbourhood associated with combinations of optic atrophy, amenorrhœa, infantilism, adiposity, and sometimes diabetes insipidus—in short, a most heterogeneous array of symptoms which had no apparent relation to acromegaly whatsoever.

The attempted reproduction of any of these mysterious syndromes by extirpation methods had been unavailing; and though physiologists had shown the existence of an active substance in the posterior lobe, it was generally believed that the organ must be vestigial, since those pioneers who had undertaken its experimental removal claimed that no symptoms whatsoever ensued. However, because of the gland's inaccessibility and small size these experiments were particularly difficult to carry out, and the results, to say the least, were undependable. Certainly, were hypophysial tumours ever to be operated upon successfully, it was necessary to know something more about the function of the gland if for no other reason than to avoid such mistakes as had been made in the process of developing the operation of thyroidectomy.

Experimental Apituitarism.—In 1907 a Roumanian investigator, Paulesco, devised a new operative approach to the canine hypophysis which enabled him to expose the gland so that it could be successfully and cleanly extirpated. The animals invariably died with a peculiar train of toxic symptoms, and he naturally concluded that the organ was essential to the maintenance of life. Here, then, out of all the vagueness of the past was something tangible, if the astonishing statement was to be believed. Dr. L. L. Reford and I in the same year undertook to repeat Paulesco's experiments and came to the same conclusions. The animals with proven total removals all died with what, in imitation of Kocher's designation for the symptoms provoked by a total thyroidectomy, we termed *cachexia hypophysiopriva*. . . . After all, the important thing to have shown is not whether the gland is actually essential to life, but that, instead of its being merely a vestigial structure of no consequence to the organism, as was claimed by Paulesco's predecessors, it is in reality an organ of extraordinary importance for the maintenance of a normal physiological equilibrium.

One would suppose, with the present-day activities of surgeons in operating upon the gland, that the clinic would by this time have provided corroboratory evidence bearing upon this matter one way or the other, just as the extirpation of the thyroid served to bring to light the essentiality of the parathyroid bodies to the maintenance of life; and though extensive operations for the removal of tumours such as the congenital lesions arising from the relics of Rathke's pouch are occasionally followed by a slow train of symptoms with fatality from inanition, I have never but once known of a clinical case in which the symptoms resembled the experimental cachexia hypophysiopriva which is so quickly fatal in animals.

This case was that of a middle-aged woman who, while in normal health, had a sudden headache which was soon followed by stupor, coma, and death in three days. The abruptness of this unexplained illness led to a detailed medico-legal examination of the body. Nothing whatever was found which could possibly account for the death but a small and unsuspected pituitary adenoma. Into this adenoma a spontaneous hæmorrhage had occurred with complete intracapsular destruction of the gland.

But to return to our laboratory studies. We naturally felt that if the train of symptoms were actually due to the removal of the gland, they could be offset by preliminary or coincidental glandular transplantation; and during the following year (1908–09), with Dr. S. J. Crowe and Dr. John Homans, an attempt was made to answer this and the many other questions which crowded in upon us. . . .

When I re-read to-day our report on the prolongation of life by transplantation of the gland after total hypophysectomy, I am less impressed with our partially successful results than I am with the many sources of confusion which beset us. We were vainly endeavouring to distinguish between the comparative importance for the maintenance of life of the epithelial *versus* the nervous portion of the gland; and in respect to the latter had been entirely misled in regard to its relation to diuresis by the studies (1901) of Schafer and Magnus—an error which at least put us in very good company. There is, however, perhaps one thing in our report which is deserving of attention to-day—namely, the appearance, in the vicinity of a transplant made into the cerebral cortex, of Herring's hyaline bodies which we regarded as evidence of activity of the posterior lobe. But this concerns a mooted question to which I shall return.

---

* Lecture I. appeared in The Lancet, Oct. 24th, 1925, and Lecture III. will appear in a subsequent issue. They are slightly abridged for issue in our columns, and will be published shortly as a small volume, dedicated to a group of young collaborators.—Ed. L.

Experimental Hypopituitarism.—These things were of minor significance when compared with a far more important observation made in the course of these experiments—namely, that many animals which survived partial hypophysectomies became in time adipose, inactive, and sexually dystrophic—a train of symptoms, in other words, resembling in many respects the confusing clinical syndromes produced by tumours of the gland which failed to cause acromegalic overgrowth, but on the contrary were accompanied by an adiposo-genital dystrophy. It is a curious fact that we had long been surrounded by these fat and lethargic animals before we really "saw" them, and before the idea burst upon us that we had actually produced states of pituitary insufficiency. . . .

An array of problems was immediately exposed for attack by this disclosure. Could the symptoms, as in the case of thyroid deficiencies, be offset by feeding of extracts or by glandular transplantations? What was the active principle with which we were dealing and where did it reside; in the posterior lobe, which alone possessed an active substance so far as physiologists could tell us, or in the anterior lobe, or in both, or were there several principles? Why should these experimental hypophysectomies have produced so many striking changes in the other ductless glands? What would be the effect on growth, provided the experiments were made on puppies rather than on the adult animals selected at random for our earliest series of experiments? Some of these questions like the last were soon answered; some of them still remain unanswered, for the riddles of physiology are not so easily solved as all that.

A series of hypophysectomies in puppies was soon carried out with Dr. Emil Goetsch, giving results, so far as the retardation of growth is concerned, in entire agreement with those reported by Ascoli and Legnani (1911) and by Aschner (1912), whose admirable papers forestalled us. We, however, doubted the truth of Aschner's contention that the effects he had obtained were due to uncomplicated total removals, in view of the operative approach through the mouth which he had employed; and yet, though we still clung to the view of essentiality of the gland, we had to admit that the fatal cachexia following its total removal in puppies was much less prompt in its onset than in older animals.

But when it occurs, this state of apituitarism, as we had observed it, is unmistakable, characterised as it is by somnolence, a slowed pulse and respiration, and a subnormal body temperature which tends before the end to fall almost as low as that of the surroundings; and Dr. Goetsch observed that the hearts of some of these animals continue to beat after death much as does the heart of a batrachian. We naturally inferred that the loss of the gland leads to some profound disturbance of metabolism and heat regulation. These effects we were inclined to ascribe chiefly to deprivation of the anterior lobe, for in confirmation of Paulesco's observation we had found that the dislodgment of the infundibular lobe (pars nervosa), leaving the pars anterior intact, led to no recognisable disturbances—an observation the more surprising in view of the active principle it was known to contain. We were not then aware, of course, that the infundibular stalk, and even the tuber, contains pathways in connexion with the pars tuberalis resembling those in the body of the lobe, and also that extracts of these areas contain traces of the active principle. Even so, it is quite probable that all of this posterior lobe tissue, pars nervosa and intermedia included, could be spared, and no untoward symptoms supervene provided the anterior lobe remains intact. . . .

Let us first of all turn our attention to this seemingly unimportant posterior lobe, to its secretory product, and the manner of its discharge.

THE PARS POSTERIOR.

As later experiences taught us, we had been barking up the wrong tree in our original conjecture that it was deprivation of the anterior lobe which caused the serious alterations in physiological equilibrium in our extirpation experiments; but leaving this aside, a more important pursuit was that in connexion with the series of animals in which incomplete extirpations had been made, particularly those with stalk division which Paulesco erroneously regarded as equivalent to a total extirpation.

In the quotation used as a caption to this lecture, Gibson makes reference to the *Rete mirabile* of the older anatomists, and Dr. Heuer, Dr. Goetsch, and Dr. Dandy made studies of the circulation of the canine gland which showed that the entire supply to the anterior lobe passed down the infundibular stalk from the Willisian vessels, whereas the posterior lobe had an additional blood-supply from vessels which enter it from behind. We therefore knew that it would be possible, in the dog at least, to divide or to obstruct the pituitary stalk without subsequent necrosis, and this led to a series of experiments the consequences of which may at this juncture be discussed.

Formation and Discharge of Posterior Lobe Secretion.—In the course of their studies here in Edinburgh on the cat's hypophysis, Schafer and Herring had called attention (1908) to the faintly staining hyaline or colloidal masses in the loose tissue spaces of the pars nervosa, and suggested that these masses might represent the secretory product of the lobe. In properly fixed preparations of the canine hypophysis we found likewise that these amorphous masses, which appear to be a product of the epithelial investment of the lobe, are at times abundant, and appear to be streaming through the loose tissue spaces which obviously radiate towards the tip of the infundibulum. This had intrigued our interest from the first, and though these presumably colloidal bodies are very elusive and are easily dissolved out of the specimens, leaving the tissue spaces empty, we nevertheless, in full agreement with Herring, frequently saw the masses in the act of seeming to extrude themselves between the ependymal cells into the ventricles.

This naturally led to an effort to detect an active substance in the fluid, and though we found this a most difficult matter, capable of false interpretations and necessitating innumerable controls, Goetsch and I came to believe that posterior lobe secretion was normally discharged into the cerebral ventricles, and ere long succeeded as we thought in demonstrating its presence in the cerebro-spinal fluid, secured from the hydrocephalic ventricles of clinical cases. Doubts as to the correctness of our conclusions promptly appeared. Edinger (1911), while admitting that the spaces in the pars nervosa appear to lead brainwards, had never seen an injection mass enter the ventricle. Carlson and Martin took exception to our findings (1911), also Houssay (1918), and even in our own laboratory the subsequent studies of Dr. Conrad Jacobson, not published till ten years later, failed to corroborate them. Dr. S. C. Harvey and I returned to the matter again in 1915–16, using the plain muscle-contracting (oxytocic) test for pituitrin without results sufficiently uniform and dependable for publication, and there the matter on our part might have rested.

However, certain more successful studies controlled by the oxytocic test were at the same time being carried out in the Pharmacological Laboratory in Cambridge by Douglas Cow (1915), who showed that the active substance in the fluid, which is most variable in amount, can be increased by the intravenous injection of certain extractives, particularly of the duodenal mucosa. And since the war, independently of one another, W. E. Dixon in Cambridge (1923) and Carl Trendelenburg in Frankfurt (1924) have taken up the subject anew with results that lend support to our original views.

Like many others (Capelletti, Petit and Gerard, Meek, Dixon and Halliburton, Frazier and Peet, to mention a few of them), we became engaged at one time or another, in the course of our cerebro-spinal fluid studies, in the elusive and uncertain pursuit of substances which might increase the flow of fluid. For reasons associated with the closed-chamber factors of the Monro-Kellie doctrine, experiments of this sort offer unusual difficulties and are prone to misinterpretation. However, we felt that we had avoided the more common sources of error by measuring the fluid production as it came from the ventricles rather than from the arachnoid cisternæ; and in our Cerebro-spinal Fluid Studies No. 8, Weed and I reported (1915) that "pituitrin," presumably from its direct action on the plexus, had a particularly marked effect in producing what we called a "choroidorrhœa." As our conclusions in this respect were not confirmed by Dandy and Blackfan (1913) and were opposed also by Dixon and Halliburton (1916) we may well enough have been misled. This, however, is less important than the confirmation by Prof. Dixon and Prof. Trendelenburg of the underlying assumption that under certain circumstances the cerebro-spinal fluid actually contains demonstrable amounts of posterior-lobe secretion.

There are, however, evidences from another source which support our hypothesis and to which we may for a moment refer. In repeating Paulesco's experiments on stalk separation, we had found on subsequent histological examination that the posterior lobe had become so extraordinarily cellular and so infiltrated with hyaline masses that we naturally came to regard this appearance as an evidence of secretory stasis, although we knew of no comparable process in connexion with any other organ of the body. We had at this time also been given opportunities to study a certain number of hypophyses from clinical cases of hydrocephalus due to tumour or otherwise in which the posterior lobe had shown a similar invasion by cells from its epithelial investment. And since many of these patients, as explained in my monograph on the pituitary disorders, had shown constitutional symptoms such as lethargy, adiposity, subnormal temperature, amenorrhœa, and so on, suggesting a deficiency of pituitary secretion, we were led to believe that under these circumstances also there must be an obstruction to the normal discharge of the secretory product from the pars nervosa.

Not only did we find, in agreement with Herring, that these hyaline bodies were greatly increased in amount after thyroidectomy, but they seemed to be even more abundant after a "near total" extirpation of the pancreas, which merely goes to show how closely the endocrine organs are functionally interrelated. But the experiments, carried out with Emil Goetsch in our 1909–10 series, which gave us the most striking picture, were ones in which a silver-wire "clip" was bloodlessly closed on the hypophysial stalk after exposing the gland by the usual operative method.

During the past year with Dr. Maddock a new series of these "clip" experiments has been conducted for another purpose, to which we shall return; suffice it to say, the histological picture of extreme cellularity of the posterior lobe with increase of hyaline and the production of great masses of colloid in the inter-glandular cleft has been invariably obtained. Certainly this striking appearance can only be interpreted as the result of an obstruction to the discharge of the products of posterior-lobe activity, or at least of products which are in transit through the lobe, for some destination or other.

Histogenesis of the Pars Nervosa.—But we know lamentably little about the actual histogenesis and structure of the neuro-hypophysis. The pineal body, a far less important organ, is much better understood and has an easily demonstrable basis of neuroglia; but there are peculiar difficulties which stand in the way of comparable studies of the pars nervosa. We have recently made an effort with the specific dyes introduced by the School of Ramón y Cajal to determine just what may be the nature of the loose tissue strands which radiate through the lobe towards the infundibulum and between which the hyaline masses accumulate. They are supposed to be neuroglial, but they do not take the specific stains for glia, and certainly the cells have none of the morphological characteristics of the glia cells. Delicate nerve-fibres of uncertain destination may be seen passing down the stalk to become lost for the most part in the upper portion of the lobe. Occasional fibrillæ which take the specific glia stains are also demonstrable in the stalk running for the most part crosswise to the course of the nerve-fibres; but neither glia nor nerve-cells can be demonstrated by methods at present at our command in the body of the lobe itself. . . .

Meanwhile, certain experimental zoologists in Germany, England, and America have hit upon a most significant consequence of posterior-lobe extirpation in the amphibia. They have shown that the lobe provides a substance which controls the pigmentary responses in the skin, for after the removal of the anlage of the epithelial portion of the hypophysis from the embryo frog, for example, the tadpole not only becomes retarded in its growth, but remains pale or albinoid owing to contraction of its cutaneous pigment cells (B. M. Allen and P. E. Smith (1916)). These pale animals serve as a most delicate indicator for posterior-lobe (pars intermedia?) secretion, for on its injection in minute amounts the melanophores expand and the animal acquires the normal colour.

This melanophore reaction to posterior-lobe extracts has not as yet, so far as I am aware, been utilised as a test for the presence of this substance in the cerebro-spinal fluid. But whatever future studies may bring forth in this respect, it may suffice to say that the posterior lobe is a unique organ surrounded by an investment of indolent-appearing epithelial cells, seemingly under the direct control of non-medullated nerve-fibres, and that stimuli of one sort or another cause these cells to divide and bud off directly into the loose tissue reticulum wherein they appear to undergo some sort of amorphous transformation as they progress towards the stalk and the infundibular cavity. At this point they not only have the appearance of passing between the ependymal cells into the ventricle, but when this apparent outlet is experimentally occluded, the gland becomes packed with the transforming cells and their secretory products. . . .

Carbohydrate Tolerance.—But I must return again to our second series of hypophysectomies to pick up the threads of another pursuit conducted with Dr. Goetsch and Dr. Jacobson, which led us to investigate the carbohydrate tolerance of our experimental animals, and from this into studies of their basal metabolic rate, which in turn was indirectly responsible for the introduction of the calorimeter into the clinic.

As already stated, we had observed, in connexion with our first series of experiments (1908–09), that definite histological changes occurred in many of the other ductless glands, notably in the thyroid and gonads, as a consequence of the hypophysectomy; and vice versa, as was well known, that changes in the hypophysis occurred subsequent to thyroidectomy, castration, and so on. We naturally wondered whether the syndrome which we had ascribed to a state of hypopituitarism might not be due to these secondary changes rather than to the primary hypophysial lesion.

All this was part and parcel of a developing conception of the inter-relations of the ductless glands, so convincingly presented ere long by the work of

Eppinger, Falta, and Rudinger. We had observed, for example, that a nearly total pancreatectomy appeared to activate posterior-lobe secretion if the associated increase in the hyaline bodies of the lobe could be so interpreted; and we also found that our adipose and lethargic animals with a pituitary deficiency seemed to tolerate the loss of the major portion of the pancreas better than normal animals would have done. We had learned also that the manipulation of the hypophysis sometimes caused a transient hyperglycæmia with glycosuria; that, corroborating Borchardt (1908), the injection of pituitrin, particularly in rabbits, had a similar effect; and, of course, we were aware that acromegaly which we had come to ascribe to a state of glandular overactivity was sometimes accompanied by symptoms resembling diabetes mellitus.

But when in a series of carefully controlled experiments we came to investigate the sugar tolerance of our partially hypophysectomised animals, we were surprised to find that the temporarily lowered assimilation limit for carbohydrates ultimately became raised, and that this increased tolerance for the ingestion of sugar could only be overcome by the coincidental administration of either pituitary or thyroid extract. Since extracts of the anterior lobe had no influence in these reactions, we accordingly were led to explain the symptoms of pituitary deficiency—the adiposity, subnormal body temperature, and so on—to an impaired oxidising or metabolising capacity of the body from loss of posterior-lobe extract, with resultant transformation and storage of sugar as fat. A definite parallelism with these experiments was found to exist in clinical cases of hypopituitarism, though under these circumstances, of course, the precise extent and nature of the functional damage could only be surmised.

As was stated in our first paper (1911) on the subject:

> "If loss or diminution of the internal secretion of the pancreas robs the tissues of their power of metabolising carbohydrates, certainly loss or diminution of the secretion of the hypophysial posterior lobe greatly enhances their power in this respect."

And this naturally led us to conjecture that an injection of the active principle of the pancreatic islets would lower the amount of sugar in the blood and that the active principle of the posterior lobe would raise it—in other words, that the two substances counteract one another, which proves to be true.

Our observations in these matters led us to a reconsideration of the so-called encephalic glycosurias which naturally date from Claude Bernard. Though his celebrated sugar piqûre was well established as a physiological experiment, it had come to be appreciated in the clinic that lesions, traumatic or neoplastic, in the neighbourhood of the hypophysis were more likely to provoke glycosuria than similar lesions near the fourth ventricle, and as early as 1898 M. Loeb had postulated the existence of a sugar centre in the tuber cinereum.

We naturally turned to investigate the manner of discharge and of action of the posterior-lobe secretion in producing hyperglycæmia. In a study of the hypophysial nerve-supply by Ehrlich's intra-vital methods, W. E. Dandy had shown (1913) that sympathetic fibres radiate along with the numerous branches from the Willisian vessels towards the pituitary stalk, and we assumed, from what was known of the nervous control of the adrenal, that the glycosuric effects of these anterior piqûres might be due to a stimulation of the autonomic fibres to the gland. We accordingly undertook to determine the pathways of these impulses, and in an elaborate study conducted in the Laboratory of Surgical Research at Harvard, with L. H. Weed and Conrad Jacobson, it was found, when what we termed "available glycogen" is present in the body, that:

1. A piqûre of the hypophysis in the rabbit is comparable, in its glycosuric response, to a piqûre of Bernard's so-called sugar centre in the fourth ventricle.
2. Stimulation of the superior cervical ganglion, by faradisation or even by the manipulations necessary for its exposure, causes glycosuria in the rabbit, cat, and dog.
3. Stimulation of the superior cervical ganglion after exclusion of all possible downward impulses to the abdominal viscera by way of the vagi, cervical sympathetic trunks, or spinal cord, leads to glycosuria.
4. Stimulation of the superior cervical ganglion after separation of all synapses of the sympathetic system by administration of nicotine causes glycosuria.
5. Direct faradic stimulation of the hypophysis itself, after exposure to a transphenoidal operation, gives glycosuria even after preliminary transsection of the spinal cord and cervical sympathetic trunk.
6. If the posterior lobe of the hypophysis has previously been removed by operation the usual stimulation of the superior cervical ganglion fails to give glycosuria.
7. Direct faradic stimulation of the hypophysis provokes glycosuria even after transsection of the spinal cord above the splanchnics.
8. A classical Bernard piqûre will likewise cause glycosuria even after transsection of the spinal cord above the splanchnics.

We naturally concluded that the infundibular lobe acts under the influence of impulses which pass from Bernard's centre in the brain-stem and reach the gland by way of the cervical sympathetic, there to liberate a chemical messenger which causes glycogenolysis, hyperglycæmia, and glycosuria; and in view of what has gone before, we assumed that this hormone was discharged into the cerebro-spinal fluid pathway.

But with all this, should these findings come to be substantiated (and so far as I know they have never been repeated) they merely throw some further light on the physiology of the posterior lobe and leave us as far as ever from an answer to the pertinent question as to whether the glycosuria of acromegaly is hypophysial or pancreatic in origin.

In an attempt to answer this question Mr. Dott applied himself a year ago, while attached to the Brigham Clinic, without coming to any definite conclusions. We know that acromegalic glycosuria is associated with a hyperglycæmia, and that it reacts to insulin as does pancreatic diabetes. We also know that an acromegalic may die from diabetic coma and no histopathological changes be apparent in the islets, though this does not necessarily imply that they may not be seriously deranged from a functional standpoint. On the other hand, as was first pointed out by J. H. Burn,[1] pituitrin will counteract the effect of insulin, an observation our early studies would fully confirm; and latterly R. C. Moehlig and H. B. Ainslee[2] have shown that the hypoglycæmic convulsions in rabbits produced by insulin may be checked by posterior-lobe extract, which causes a rise in the blood-sugar. Moreover, we know that acromegalic diabetes is capable of spontaneous recovery. . . .

Before leaving this general discussion of the posterior lobe and its manifold activities, there is still another subject which deserves discussion, for it has led to discordant views. It concerns the much-mooted question of the hypophysial polyurias.

Diabetes Insipidus.—Is this disorder primarily neurogenic or primarily hypophysial in origin? This question has divided students of the subject into two opposing camps. Indeed, as may be recalled, a similar discussion once raged in regard to Graves's disease which some still attribute to a neurogenic disorder in which the thyroid plays merely a secondary rôle.[3]

[1] Journal of Physiology, June, 1923, lvii., 318.

[2] Jour. Amer. Med. Assoc., May, 1925, lxxxiv., 1398.

[3] In this connexion should be recalled Cannon's ingenious experiments on cats in which the phrenic nerve and the cervical sympathetic were anastomosed low on one side of the neck. By this procedure the rhythmic efferent impulses associated with respiration passed along the sympathetic, presumably to the thyroid, and provoked a most curious state with excitability, rapid pulse, increased metabolism, and so on, which was interpreted as an evidence of experimental hyperthyroidism. Dr. Gilbert Horrax in 1914, at my suggestion, repeated these experiments, and, as a control, removed the thyroid lobe on the side of the anastomosis. His results (unpublished) were the same as those obtained by Cannon. We naturally claimed that our friend the hypophysis was more concerned than Cannon's friend the thyroid. There the matter rests.

It must have occurred coincidently to many of those who were interested in the subject of diabetes insipidus that the supposed renal sources of the disease would have to be abandoned. For our own part, the early experimental hypophysectomies, with their resultant polyuria, had led us definitely to associate this symptom with a functional derangement of the gland, and this view was supported by certain clinical observations in which patients with bitemporal hemianopsia and primary optic atrophy, unmistakably due to tumour in the region of the hypophysis, had at the same time persistent polyuria of high degree. We have seen that non-myelinated nerve-fibres pass down the infundibular stalk, and it is perhaps natural that the hypothalamus (tuber cinereum) whence they may originate should be a favourite place for the predication of centres such as the sugar centre of Loeb, of which we have already made mention. Erdheim, I believe, was among the first to suggest that an injury of these centres was responsible for these polyurias, rather than that they were due to an actual pituitary derangement; in other words, that they were of nervous rather than glandular origin. He had arrived at this conclusion, I assume, during the course of his well-known studies of the congenital cysts of the infundibular region rather than from the actual identification of any centres by physiological experiments. However this may be, the view doubtless influenced other Viennese investigators, among them Aschner, who explained the polyurias following his experimental hypophysectomies on the same basis, just as did Narbut the diminished oxygen consumption shown by these same animals. . . .

Personally, I find myself in discord with these views both on experimental and clinical grounds; on a pure neurogenic basis it is difficult to explain why the supposedly hypothalamic polyuria should be promptly checked by the administration of posterior-lobe extract. After all, it is perhaps an academic question whether an injury to adjacent nerve-centres whose very proximity is enough to suggest that they preside over the activities of the gland, or whether damage of the gland itself by injury or disease is the actual cause of a given syndrome.

But the whole subject of the non-diabetic polyurias has from the first been in a tangle of inconsistencies, and indeed it was not until 1912 that studies such as those by E. Frank in Minowski's laboratory served to point strongly towards their hypophysial rather than renal origin. The chief source of confusion lay in the fact that diuresis provoked by posterior-lobe extracts is but a transient effect, and it was not until the acute physiological experiments on which this opinion was based were checked by long-enduring observations that the extract was found to have precisely the reverse effect—namely, to provoke an oliguria rather than a polyuria. The experiments of Ketil Motzfeldt carried out in the Harvard Laboratory (1917) were among the first to make clear that pituitrin actually has antidiuretic properties, and thus to explain the apparent disharmony of the physiologists and clinicians; for it had been clinically observed by both Farini and Von den Velden (1913) that the extract given hypodermically, contrary to expectation, would actually inhibit the polyuria of diabetes insipidus.

This was a disclosure which justifies all the time and thought which many have given to the subject of these polyurias, for it has put into our hands what Andrew Cameron was after—namely, a practical therapeutic treatment for the amelioration of a most distressing disease. Still, we are no nearer an actual explanation of diabetes insipidus, for if the disorder is due to an injury of some centre in the tuber cinereum, it is remarkable that it is so rarely an accompaniment of the craniopharyngeal-pouch tumours which compress and deform not only the tuber where the centres supposedly lie but the hypophysis itself.

It was for the purpose of reconsidering the interpretations which Bailey and Bremer had put upon their experiments, and in the hope of reconciling our conflicting views on the subject, that Dr. Maddock and I this past winter have made a control series of experiments in which, as stated, we have reverted to the method employed in our earlier studies of placing a silver "clip" on the hypophysial stalk. By the aid of Weed's brain-shrinking method these operations are conducted more easily to-day than they formerly were, and the "clip" can be closed on the stalk of the dangling canine gland quite bloodlessly and without any appreciable or histologically demonstrable injury of any adjacent structures. When this procedure is carried out, precisely the same train of symptoms is evoked that Bailey and Bremer describe—viz., a prolonged polyuria with subsequent tendency to adiposity.

Probably, therefore, the effects are the same whether produced by: (1) an injury to the hypothalamic centres; (2) a "block" of the nervous impulses with obstruction of the secretory products in the posterior lobe; or (3) a partial hypophysectomy with actual removal of the lobe. In other words, a break in the mechanism of posterior-lobe secretion from nerve-centre to gland produced by any agency tends to upset the normal water balance and to cause an hypophysial polyuria; and, conversely, the administration of pituitrin serves to check the experimental polyuria thus produced wherever the break in the mechanism may have occurred.

This explanation at least harmonises the differences which lay between my own preconception in this matter and the views of my pupils. But it will not, I fear, quite satisfy those who, like J. J. Abel, if I understand him correctly, believe that the responses are entirely by chemical messengers and that the direct nervous influences may be wholly disregarded.

The antidiuretic property we have been discussing is but one of many which extracts of the posterior lobe possess, and some of which are already utilised for practical therapeutic purposes. The attention of the pharmacologist has tardily become focused on a study of the biochemical nature of the substance or substances responsible for these various reactions. Some have postulated the existence of three or four separate hormones. Others, like Prof. Abel, believe that there is only one specific hormone which alone, as appears to be the case with his tartrate, is capable of evoking all the known responses, cardiovascular, antidiuretic, oxytocic, respiratory, and melanophore-expanding.

THE PARS ANTERIOR.

In what has gone before overmuch has perhaps been said in regard to the physiology of the pars nervosa, and we may now turn to the epithelial lobe, where there are fewer functional straws at which to grasp, though there are many reasons for ascribing to this portion of the gland the premier rôle among the endocrines—if, with all said and done, we are entitled to consider separately the function of the two or three anatomical subdivisions of the gland. However this may be, the customary physiological weapons of attack are unavailing in the case of the pars anterior and we must have recourse to roundabout ways if we would spy into its secrets. The fact that we are not all in agreement as to whether the various cellular elements, chromophile and chromophobe, comprising this highly vascularised lobe represent different stages of activity of a single cell type or are cells of quite different function, shows the present great limitations of our knowledge. As Abel has said in regard to the posterior lobe hormone, there are Unitarians and Trinitarians among us.

Metabolism Observations.—In considering the relation of the posterior lobe to the utilisation of sugars, the question was discussed whether the glycosuria of pituitary disease should properly be regarded as an hypophysial or a pancreatic effect. A similar question is naturally raised in regard to the alterations which the clinical cases show in their metabolic rate. Are they primarily hypophysial or secondarily thyroid in origin? To this subject we may now turn for a moment. . . . . .

While we were engaged in our studies of carbohydrate tolerance in 1908–10, I knew nothing about metabolism estimations, hardly knew, indeed, what the term with its modern implications signified. We had observed in the clinic that outspoken states of hypopituitarism, in addition to the adiposity and sexual dystrophy which they showed, were accompanied by periods of profound and long-enduring somnolence, by a slowed pulse and respiration, by a subnormal body temperature, and by an apparent insensitivity to external stimuli—states comparable to those of our experimentally hypophysectomised animals. Certainly these individuals were burning their tissues at a low fire, and it was perhaps not unnatural that the clinical syndrome should have suggested resemblances to what we vaguely knew as the state of hibernation. Since the experimental extirpation of no other ductless gland except the hypophysis, so far as we knew, caused this particular train of symptoms, Dr. Goetsch and I were led to make some studies in this direction, and we found, as others had found before us, that in the hibernating state the ductless glands, notably the hypophysis and gonads, appear to be in a resting stage, whereas at the period of awakening they become markedly hypertrophied; but aside from these simple histological studies which served to disclose these facts, we found ourselves dealing with a subject of unanticipated difficulties which was intertwined with chemico-metabolic problems beyond our reach.

A more important lead came from another direction, for Dr. John Homans, after his year in the Hunterian Laboratory, enlisted the interest of Francis Benedict in the subject of our dyspituitary dogs, whereupon Dr. Benedict devised a respiration calorimeter for determining the carbon-dioxide production of small animals. With the aid of this apparatus, as described in their detailed report (1912) from the Carnegie Nutrition Laboratory, they observed, among the other general effects of a partial hypophysectomy in puppies heretofore discussed, that in the course of time there was a marked post-operative fall of the total metabolism as measured by the carbon-dioxide production per kg. of body-weight per hour, a fall which was the more striking owing to the amount of inert body fat the animals gradually acquired. . . .

It may suffice to say after this lapse of a dozen years that the hypopituitary cases show, as did Homans's animals, a lowered rate, whereas the metabolism in the active stages of acromegaly is raised, though never to so high a percentage as may be seen in hyperthyroidism. The extremes which have been observed are −39 for the former and +65 for the latter.

But this does not answer the question at hand—Is the increased rate in acromegaly due to a secondary thyroid hyperplasia rather than to some influence on metabolism possessed by the hypophysis itself? We, of course, are all aware that acromegaly has notable polyglandular manifestations, and I believe the view is held in the Mayo Clinic, where Dr. Boothby and Miss Sandiford have gone, that the increased metabolic rate shown by these cases is a secondary phenomenon; for it has been observed that removal of the enlarged thyroid of an acromegalic lowers the rate. But even this does not settle the point. The only proof could come from a lowering of metabolism by the partial removal of an hypophysial adenoma leaving the enlarged thyroid untouched; and an example of such an effect has been cited in a recent study of the pituitary adenomas by Dr. Bailey and Mr. Dott. . . .

Hypophysial Relation to the Glands of Sex.—Among the most definite consequences of hypopituitarism, whether produced by experimental procedures, by glandular tumours, even by hydrocephalus, so frequent a source of interference with the gland's activity, are the secondary effects on the gonads to which attention has often been called. Infants fail to acquire normal sexual adolescence; adults lose their sexual desires and potency; amenorrhœa in women is one of the first tell-tales of disturbed function.

It is difficult to tell whether these symptoms and the histological changes which accompany them are ascribable to the anterior or posterior lobe or to the combined action of both, but reversible effects show at least that the anterior lobe is an important element. Erdheim and Stumme, for example, first clearly showed (1909) the remarkable alteration in the cells of the anterior lobe associated with the amenorrhœa of pregnancy. The secondary enlargement of the hypophysis in eunuchs had been noted before this by Fischera (1905) and by Tandler and Gross (1905); and it is stated that in castrated hens the gland almost doubles in size. Indeed, the hen's plumage acquires male characteristics just as in certain clinical endocrine disorders we may see a suggestive reversion of the female to the male type and vice versa. All told, modern experiments on the gonads and sex physiology read like a story from the Arabian Nights.

Naturally, while we have been waiting for the biochemist to isolate the active principle or principles of the gland, efforts have been made both in man and animals to see what would be the effect of prolonged feeding of pituitary substance and of glandular transplantations. The attempts have been innumerable, and the results, so far as growth is concerned, quite negative, though Prof. Schafer was led to believe that "the addition of a small amount of pituitary substance to the food appears to favour the growth of young animals." . . .

In 1913–14 Dr. Goetsch took this matter up anew. In a time-consuming and most carefully controlled study of a series of young rats of known pedigree and growth curve he found that the daily oral administration of bovine anterior lobe extract during the preadolescent period had a remarkably stimulating effect upon the development of the reproductive glands of both sexes, shown not only by their early sexual maturity and their precocity in raising families, but by demonstrable histological evidences of precocious ovulation and spermatogenesis. . . .

The Hypophysis and Growth.—The experimental zoologists have turned their attention to the relation of the pars anterior to growth, and P. E. Smith (1917) showed that the retarded development of hypophysectomised tadpoles could be accelerated if they were fed upon certain residues of the anterior lobe. But the most convincing experiments yet conducted have been those of Herbert M. Evans (1922–5). Dubious of the effects to be expected from the oral administration of pituitary extracts in the higher animals, Evans gave to a series of rats daily intraperitoneal injections of the emulsion of fresh bovine gland, and succeeded in producing such marked overgrowth as to justify him in designating the condition as one of actual gigantism. Thus the assumption that the overgrowth of clinical acromegaly and gigantism is an expression of hyperpituitarism receives its first really striking experimental proof. . . .

Encouraged, as others doubtless have been, by Dr. Evans's remarkable results, we have undertaken on our own account some further studies in regard to growth. Dr. Leo Davidoff, who has for the past two years been concentrating his attention on our series of acromegalics, undertook to see, by using Evans's methods, whether in animals, which had presumably attained their full stature, acromegalic characteristics might not be observed. But this proves to be a most difficult quest; and since preparations such as Evans employed are not tolerated by larger animals such as rabbits, cats, and dogs, when given intraperitoneally, we cast about to find some standard pharmaceutical preparation which at least might appear to possess traces of an active anterior lobe principle.

One of these preparations was found to have a prompt effect in checking the œstral cycle in female rats, and though this in the light of Goetsch's experiments would seem contradictory, it at least showed the presence of an active substance of some sort. Accordingly, a series of rats was subjected to prolonged intraperitoneal injections with results which suggested, at least, that the preparation contains the growth principle as well. The experiments, indeed, taken in conjunction with P. E. Smith's experiences on hypophysectomised tadpoles, were regarded as sufficiently encouraging to justify an attempt in the clinic to stimulate growth in one of our little patients whose stature for the two years following a successful removal of a Rathke's pouch cyst had remained unchanged.

These children are peculiarly coöperative and intelligent patients, and this particular child submitted, with his parents' consent, to receiving an intraperitoneal injection of 5 c.cm. of this substance every second day for a period of over two months. We had hoped that the effect of the substance, were it actually present, would be more marked in a case of pituitary infantilism than in a normally developing individual; but no effect whatsoever was observed. We evidently have much more to learn about these extracts before we can adopt them to clinical use, and the many apparent contradictions had far better first be untangled, so far as possible, in the laboratory where observations can be controlled. . . .

SURGICAL CONSIDERATIONS.

The Tumours.—As emphasised in many places, had it not been for the tumour and its local pressure effects the surgeon would hardly have come to meddle with the questions which up to this point have been under consideration. Having been drawn in, because there were mechanical difficulties to overcome, it was inevitable that he should take something more than a mechanical interest in the subject. So it was with the thyroid. Certain goitres by displacing and flattening the trachea caused a mechanical dyspnœa which could only be relieved by some surgical procedure. Kocher and the Reverdins first had the temerity to undertake operations under these desperate circumstances, and it is common knowledge that clues for solving some of the thyroid and parathyroid puzzles were thereby supplied.

But the thyroid goitre offered a simple problem compared to that of the hypophysial goitre. One was exposed to view for the layman to diagnose; the other was concealed and affected not only the eyes of its victim, but obscured the vision of the professional observer as well. Consequently those who now have on their hands the responsibility of tardily developing the operative treatment of hypophysial disorders may comfort themselves by the recollection that those who have relayed to their successors the surgery of the thyroid adenoma had a 20-year head start, and our problem is a far more complicated and difficult one. We meanwhile have profited greatly by their experiences; have more or less followed in their footsteps and avoided some of the pitfalls they had pointed out.

I have already touched on the fact that one or two of the earliest operations on the hypophysis were in cases of acromegaly, and that those who had undertaken them were led to believe that there had been a definite amelioration of the constitutional as well as of the local symptoms. But these were precocious steps taken in imitation of partial thyroidectomy for Graves's disease, and as we now understand the matter they were steps taken out of turn. For even to-day one may as well admit that the treatment of pituitary tumours consists of little more than the prevention or relief of the local pressure-effects of pituitary or parapituitary tumours. True, this is a great boon, and the neuro-surgeon now shares with ophthalmic surgeons the thrills and satisfactions of restoring vision to persons on the verge of blindness.

But in his desire to share in this satisfaction, the surgeon may get into infinite trouble unless he has some knowledge of just what he is after. I recall the remark made by a companion while watching a small dog bounding across the fields in pursuit of a railroad train: "I wonder what he'll do with it when he catches it." So it behoves us to be thoroughly aware of the nature of the various tumours of the hypophysial neighbourhood, and there are perhaps three main groups: the suprasellar meningiomas and craniopharyngeal pouch tumours which, in addition to their local pressure effects, may evoke typical hypopituitary syndromes, and, thirdly, the hypophysial adenomas proper, some of which give the reverse clinical picture. Without a definite understanding of the precise situation, behaviour, and manner of growth of these several lesions, it would be foolhardy to attack them; and the surgeon consequently must know his morbid anatomy no less well than his physiology of the gland.

We, of course, are indebted to the pathologist for our primary conception of these several lesions, but by the time they have come under his observation it is inconceivable that they could ever have had any surgical bearings. The fairly common suprasellar meningioma, which takes its origin from the arachnoidal cell-nests as described in the preceding lecture, may slowly in the course of years attain the size of a fist before it causes death; and yet these lesions when small are not only capable of being diagnosed, but can be exposed and totally removed with preservation of vision in spite of their awkward position between hypophysis and chiasm.

The Congenital Cysts.—And the same is true of the more common craniopharyngeal pouch cysts first clearly described by Erdheim in 1904, though there is very little in the literature concerning the surgical treatment for these remarkable congenital lesions. They usually, though not invariably, begin to manifest their presence in preadolescent life both by local signs of tumour as well as by their pressure-effects on the hypophysis as a whole. Hence in these little patients one may see in most outspoken form the combined syndrome of anterior-lobe disturbance (sexual and skeletal infantilism) and of posterior-lobe disturbance (adiposity, a high sugar tolerance, a low metabolism and sometimes diabetes insipidus).

These lesions, moreover, are usually suprasellar and need not in any way deform the sellar outlines as shown by the X ray. But there is a tell-tale of their presence which to-day is demonstrable in fully 80 per cent. of the cases owing to the refinements of roentgenological technique which the invention of the Potter-Bucky diaphragm has made possible. This concerns the deposits of lime salts which occur in connexion with the keratinised epithelial lining of the cysts. The diagnosis, however, is not quite so easy as all this, for sometimes the congenital tumour does not ride so high, but may actually develop within the capsule and distend the sella precisely as does the more common adenoma. . . .

With the congenital cysts, however, the difficulty is not so much in the diagnosis as in knowing how to deal with the cyst when it is exposed. The mere evacuation of its contents gives only temporary relief since there is an early refilling. Extirpation is necessary, and this is difficult because of the relation of the tumour to the optic nerves. These cases, of course, are operated upon from above by an osteoplastic approach; different surgeons advocate different procedures, but personally I prefer to come down upon the lesion from in front rather than from the side.

Though I do not intend to bore you with descriptions of operations, it may be said that the chiasm, in justification of its name, represents the crux of the matter. Though some of the cysts have sufficiently thin and tough walls so that after evacuation they may be drawn out from between the distorted optic nerves practically intact, more often the calcareous and keratinised part of the wall is so adherent and extensive as to make this impossible. I have never quite had the courage to take what may be the proper step under these circumstances—namely, to split the chiasm fore and aft, thereby committing the patient to a permanent bitemporal hemianopsia, but at the same time giving free access to the mesially placed tumour which at times may assume astonishing proportions. We have seen such a cyst as large as a tennis ball, its walls a solid mass of calcification.

After all, a permanent bitemporal hemianopsia is preferable to the recurrence of symptoms so apt to take place. Only one anatomical structure stands in the way of such an operation—the anterior communicating artery which lies stretched out across the elevated surface of the chiasm, but this vessel, as I have found, can be easily "clipped" and divided. Thomas Willis would be interested to know that a portion of his circle, from which the spokes of the *Rete mirabile* of his predecessors pass to the hypophysis has actually come, after all these years, to be an important factor in a surgical operation.

The Adenomas.—These present quite a different surgical problem from the congenital cysts, and, strictly speaking, should be the main object of our discourse, for they are by far the more common lesion, and primarily rather than secondarily affect pituitary function. They have so recently been made the subject of a detailed report by Mr. Dott and Dr. Bailey that it is hardly necessary to say more. Dr. Bailey has come to believe from a histopathological review of the adenomatous tissues in our collection that he can identify a "mixed type" of adenoma. This differs from the chromophile adenoma of acromegaly and the chromophobe adenoma characterising hypopituitarism, in that a peripheral rim of eosinophilic granules still persists about the cell; and he and Mr. Dott feel confident that this particular type of adenoma serves to explain those mixed clinical syndromes in which traces of acromegaly are seen commingled with the clinical evidences of hypopituitarism.

It is our custom and preference to approach these glandular tumours by a method called transsphenoidal. A small incision is made under the lip; the mucous membrane is separated on each side so that the operative approach is by way of the nose but does not actually enter the nasal cavities. A speculum is inserted, the anterior wall of the sphenoidal cells removed, the thin bulging floor of the sella chipped away, the dural encasement incised, and such an amount of the gland as is thought sufficient to relieve pressure is then spooned or sucked away. It sounds simple, and in a favourable case may be so. What is more, the convalescence is usually rapid and uneventful with rapidly widening fields of vision.

One would suppose that these operations, which necessarily open the enveloping arachnoidea of the gland, would be attended by great risk of meningitis. As a matter of fact they are not, and the mortality of the series taken as a whole, including the early operations, which were foolishly done on patients often in extremis due to a then poorly understood intracranial extension of the growth, is now approximately 7 per cent.[4] However, in the last 50 successive transphenoidal operations there has been only one fatality, which brings the operative mortality of the more recent years well within bounds—namely, at 2 per cent. But what is of more importance is the fact that in about 70 per cent. of all these cases there has been a vast improvement of vision. This, of course, is the proof of the pudding.

In the days when we first began to study these cases in the surgical wards at the Johns Hopkins, the perimeter was a dusty instrument on a shelf rarely used except for demonstration either in the neurological or ophthalmological clinics. To-day we could not get on without it, and the perfected technique of taking the field peripheries which was elaborated by Clifford Walker during the years he was a member of my staff continues to be employed, so far as they are capable of it, by my successive neurosurgical residents. And a neurosurgical group has scarcely less need of the ophthalmoscope and the calorimeter and other instruments of precision. Nor should the microscope be forgotten, for the histopathology of these lesions is no less important to him for diagnosis and prognosis. Subdivisions of responsibility in the routine handling of large groups of patients is probably necessary—diagnostic tests by a series of special people, an operation by another set, the pathological report by still another. But any such system, when progress is to be made in a new field, is unworkable.

I was once told by Prof. Kocher, who I suppose had his experiences with the thyroid in mind, that no satisfactions in medicine were so great as those which came from concentration upon and the mastery of a small subject, and that this necessitated an approach from all aspects, diagnostic, experimental, pathological, and therapeutic, not the least important part of which at one time or another in the history of the subject was likely to be surgical.

It will be given to few to play such an important part in the history of any subject as that which he played in the case of the thyroid disorders. The best that people of lesser intellects and industry than he possessed can do is to come as near to this goal as their abilities permit. But the surgery of the hypophysis at the present time, as I am sure he felt about the surgery of the thyroid in his early days, is practically in the "stone age" of its development. The time will come, ere long perhaps, when the biochemist will have shown us how to cure most of the common functional adenomas of both of these glands without surgery. Prevention will then come in its turn to supplant even these eagerly sought medicinal cures, and this will represent the "golden age" of the subject which not even the youngest of us here are likely to see.

---

[4] Out of 219 cases of pituitary adenoma, 214 have been operated upon. The transphenoidal route has been used in 203 cases with 15 fatalities, giving a mortality of 7·38 per cent. The transfrontal route has been used in 35 cases with two fatalities, giving a mortality of 5·7 per cent. The total operative mortality for the entire series is therefore 7·1 per cent.

Remarks

ON THE

PHYSIOLOGY OF MUSCULAR ACTION.

Presidential Address given before the Section of Orthopædics, Royal Society of Medicine,

By A. S. BLUNDELL BANKART, M.Ch. Camb., F.R.C.S. Eng.,

ORTHOPÆDIC SURGEON, MIDDLESEX HOSPITAL; SURGEON, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL AND HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

It is not long since a well-known surgeon said that surgery was anatomy, pathology, and common sense, while, as for orthopædic surgery, it was nothing but anatomy and common sense. This is a common misconception of orthopædic surgery as a sort of mechanical craft, although the proceedings of this Section alone would convince anyone of the wealth of pathological material with which we have to deal. But orthopædic surgery is more than that. The ultimate aim of orthopædic treatment is *restoration of function*, and those who profess to deal with disorders of bodily function must have some knowledge of the normal functions of the body, that is physiology.

Ten years ago Sherrington remarked that "the publications of zoologists and clinicians do not commonly meet quickly." It is rather humiliating to discover that some cherished belief, some generally accepted theory, and perhaps the treatment based upon it, is about 20 years behind the known facts of physiology. So I thought that I might use this occasion to direct your attention to some bearings of physiology on orthopædic surgery rather with a view to stimulating thought and discussion than with any idea of presenting new facts. And, as so much of our work is concerned with the action of muscles, and time is short, I will confine my remarks to this important part of the subject—the activities of muscle.

Some years ago I drew attention to the significance of Sherrington's work on the postural activity of muscle—work which has not only thrown new light on the nature of posture and the disorders of posture, but has compelled us to revise entirely our ideas concerning the action of muscles generally.

TWO KINDS OF MUSCULAR ACTIVITY.

It is now known that the skeletal muscles exhibit two kinds of activity. The one is phasic—quick and transient and concerned with the execution of movement; the other is tonic—relatively slow and prolonged and concerned with the maintenance of posture. These two kinds of muscular activity are physiologically quite distinct. They differ in their effects, in their metabolism, in their nervous mechanisms, and recently it has been said that they are anatomically separate. But of this I shall have more to say presently.

Muscle is a specialised substance which has the property of altering its shape in response to a nervous impulse. This alteration in shape, which gives rise to movement, is due to a change of surface tension brought about by electro-chemical means upon the surface of the muscle-fibres. It should be noted that a muscle-fibre undergoes no change in volume; it merely becomes more spherical or less spherical, as the case may be. Both contraction and relaxation of muscle are thus active processes. The change is accompanied by a great expenditure of chemical energy, by the production of heat, and by the consumption of oxygen and output of CO_2. If unduly prolonged or frequently repeated, this kind of activity becomes rapidly fatigued, and the muscle becomes incapable of further action until it has rested.

Except that smooth or unstriated muscle has a certain power of automatic action, the only natural stimulus of muscle is a nervous impulse. The response to a single nervous impulse is a single twitch. Voluntary contraction is a tetanus—that is, a summation of twitches brought about by a rapid succession of impulses down the nerve-fibre at the rate of about 50 per second.

It was shown by Keith Lucas that the propagated disturbance in a nerve-fibre is always of the same intensity, regardless of the strength of the stimulus. It follows, therefore, that the nervous impulses which reach muscle-fibres are always of the same strength. It is now known, too, that muscle contracts on the "all or none" principle—that is, if it contracts at all it contracts for all it is worth. This used to be thought to be a peculiarity of heart muscle, but it is now known to be true of all muscle.

There are, therefore, no degrees of contraction in normal muscle-fibres; there is no such thing as a strong contraction or a weak contraction, apart from the size of the muscle-fibres concerned. The absolute strength of a muscle is determined by the size and the number of its muscle-fibres. The different degrees of response that may be obtained on stimulation of a motor nerve are due to the number of nerve-fibres, and therefore the number of muscle-fibres, excited by different stimuli. A strong stimulus excites many or all of the nerve-fibres and therefore brings into action many or all of the corresponding muscle-fibres, and the result is a strong contraction of the muscle; while a weak stimulus excites few nerve-fibres and brings into action few muscle-fibres, and we get a weak contraction.

For a given muscle, therefore, the strength of a contraction is the direct expression of the number of nervous impulses sent into it. Much of what is commonly spoken of as muscular weakness has nothing whatever to do with the muscles, but is entirely a question of nervous energy. I would add here that we speak loosely—perhaps conveniently—of the education or re-education of muscles. But, of course, you can no more educate a muscle than you can educate a liver or a bone. The only thing that you can educate is a reflex—that vital process which occurs exclusively in connexion with the terminations of a nerve-cell. It is not sufficiently recognised that the basis of so-called remedial gymnastics and re-education is neurology.

The muscles on one aspect of a joint are sometimes called the antagonists of those on the opposite aspect. This is an unfortunate choice of a word to express a mere anatomical fact. Muscles do not oppose one another, they coöperate. When movement takes place, the contraction of one group of muscles is accompanied by reciprocal elongation of the opposite group, and the nervous impulses which cause the latter to relax are the direct outcome of those which make the former contract. Even when muscles on both sides of a joint contract simultaneously, as in the fixing of a posture, this is not antagonism, but a concerted action. Paralysis of reciprocal innervation gives rise to a grave functional disorder, which we call spastic paralysis. This, if you like, may be called antagonism.

Now, speaking still of movement in muscle-fibres, it is well known that the nature of the response differs in different kinds of muscle. Thus the typical twitch in striated or skeletal muscle is a sudden quick contraction which rapidly reaches its maximum and almost as rapidly falls away; while the contraction of smooth or unstriated muscle is relatively slow and prolonged, presenting a gradual rise and a still more gradual fall. What is the difference? Both kinds of fibre are subjected to a similar change of surface tension; why does one respond quickly and the other slowly?

I introduce this question here because, as we shall see, it has an important bearing upon another question which has become prominent recently—namely, the question of the dual structure of muscle. Note that we are now considering the phenomenon of movement in two different kinds of muscle-fibre. It seems that the different rates of response to stimulation of striated and unstriated muscle respectively can only be due to the fact that one kind of fibre offers more, and the other less, resistance to the force which brings about its change of shape. In other words, it is a question of the internal resistance or viscosity of the cell substance. Now, viscosity is a physical property which can be made to change, and it is significant that in certain circumstances, for example, in veratrin poisoning and in the condition known as decerebrate rigidity, the contraction of striated muscle approximates in character to that of unstriated muscle.

POSTURAL ACTIVITY OF MUSCLE.

The postural activity of muscle is concerned, not with the execution of movement, but with the prevention of movement—that is, the posturally acting muscle develops within it a state of tension or resistance to a force which is trying to stretch it without itself necessarily undergoing any outward change.

The most remarkable features of this activity are: (1) The "lengthening" and "shortening" reactions by which the muscle adapts itself to different lengths while maintaining the same tension. It was this property which led Sherrington to apply the term "plastic tonus" to postural activity. (2) The fact that it entails hardly any appreciable increase of metabolism, so that it can be maintained almost indefinitely without exhibiting any signs of fatigue.

Now, this state of tension or resistance might be brought about by a change of surface tension of the muscle-fibres, similar to that which produces movement—by an isometric contraction of the muscle, in fact—and this actually is the means by which resistance is offered to a force greater than that which is developed in ordinary postures. But, as we have seen, this phasic activity of muscle is accompanied by a great expenditure of energy and by the rapid onset of fatigue, so that it cannot be maintained for long. On the other hand, the postural activity of muscle is maintained with hardly any perceptible increase of metabolism, and it is almost incapable of fatigue.

Clearly we are dealing here with quite a different mechanism. It has been likened to a ratchet or catch mechanism by which a state of tension may be maintained indefinitely without the expenditure of any energy. In the living cell such a condition can be attributed only to some change in the physical characters of the cell substance.

The viscosity of cell substance is known to vary significantly at different times in the life of the cell, and Bayliss showed that visible changes in viscosity may be brought about by disturbances such as are called stimuli. It is known that colloidal solutions in certain circumstances have the property of setting or clotting—like the setting of a solution of gelatin on cooling—and that they then offer a resistance to deforming forces many times greater than they could while in the fluid state. This is a physical reaction and reversible, and it has been suggested that the postural activity of muscle is a similar reaction controlled by its special nervous mechanism. So that in the language of physical chemistry the postural activity of muscle consists of a change from sol to gel, and herein lies the explanation of a state of tension or resistance developed without preceptible increase of metabolism and maintained without fatigue.

From the physiological point of view there appears to be no reason why these two functions, movement and posture—the one a change of surface tension and the other a change in the molecular arrangement of the cell substance—should be performed by different structures, by different parts of the muscle-fibres, as originally suggested by Bottazzi, or by actually different muscle-fibres, as recently claimed by Hunter. Indeed, in view of the close coördination that exists between movement and posture in higher animals, an anatomical separation would appear to be a positive disadvantage. Such a primitive arrangement obtains in some invertebrates in whom these functions are of the simplest order. But, in vertebrates, so far as can be made out, movement and posture are different reactions of the same muscle-fibres. Indeed, the more closely the question is studied, the more it appears that postural activity is but a further degree of that viscosity or internal resistance which we have seen is a variable quality in muscle-fibres performing movements.

THE QUESTION OF SYMPATHETIC INNERVATION.

It is necessary, therefore, to examine somewhat critically the evidence recently put forward by Hunter and Royle in support of their contention that the functions of movement and posture are performed by entirely different sets of muscle-fibres, the movement fibres being supplied by the ordinary spinal nerves and the postural fibres by the sympathetic. An excellent review of the whole question by Walshe has just appeared in the last number of *Medical Science, Abstracts and Reviews*,[1] so I shall be very brief.

It has long been known that the skeletal muscles receive accessory, non-medullated, or sympathetic nerve-fibres in addition to the ordinary spinal nerves. These consist of fine fibres connected on the one hand with the perivascular sympathetic nerve plexuses and ending in the muscle-fibres independently of the motor end-plates.

The presence of these fibres seems to have caused some surprise, and there has been much speculation as to the functions which they could possibly serve. But there are two points which I have not found mentioned in any of these discussions. First, are not all functioning tissues supplied by the sympathetic? Function is accompanied by an increased blood-supply which is ensured by reflex vaso-dilatation through the sympathetic. Second, in warm-blooded animals the skeletal muscles are the chief source of heat. Heat is conserved by muscular activity and peripheral vaso-constriction, while heat loss is promoted by muscular relaxation, peripheral vaso-dilatation, and sweating. These are nicely coördinated sympathetic reactions, and it is therefore not surprising to find that sympathetic nerve-fibres go to the skeletal muscles. It should also be noted that it is phasic, not tonic, muscular contraction that gives rise to heat.

Hunter's work started from the observation of Kulchitsky that "the medullated and non-medullated fibres never end in the same muscle-fibre." This is at best a negative observation and contrary to the findings of Boeke, Agduhr, and others. In fact, Hunter himself said that the question must be decided on the experimental evidence.

EXPERIMENTAL AND CLINICAL EVIDENCE.

For a criticism of the experimental and clinical evidence in detail I shall refer you to Walshe's excellent paper.[1] Here I shall content myself with quoting his main conclusion that the experiments and the clinical cases are not conclusive, and the descriptions thereof contain details not explicable on any theory of sympathetic function. Others working on the same lines have failed to obtain results approaching those claimed by Hunter and Royle. In short, it may be said that the whole weight of evidence—histological, experimental, and clinical—is against the hypothesis of a specific innervation of the tonic or postural activity of skeletal muscle by the sympathetic; against the separation of muscular tone into two elements—"contractile" tone and plastic tone; and against the conception of a dual structure of muscle.

To this I will briefly add my own small experience on the clinical side. I have done the operation of sympathetic ramisectomy ten times, lumbar ramisectomy nine times, and cervical ramisectomy once. All but one were typical cases of spastic paralysis exhibiting the plastic tonus described by Sherrington. The odd case was one of paraplegia in flexion with pronounced flexor spasms, and it is interesting to note that the result, such as it was, of the operation in this case was at least as well marked as in any other case that I have seen. In four cases no appreciable effect on the muscular condition was noted after operation. In six there appeared to be a definite, though slight, diminution of the muscular spasm. It has seemed to me to be about comparable to the amount of relaxation that might be expected from the accompanying vaso-dilatation. In no case have I been able to persuade myself that it was of real benefit to the patient.

This experience seems to be similar to that of all others who have tried the operation of sympathetic ramisectomy in this country and in America. Similar results were also obtained in the two cases chosen by Hunter and Royle out of a series of 25 cases specially selected for the purpose, and operated upon by Royle in Boston in October, 1924. It therefore seems unlikely that this operation will survive long as a method of treating spastic paralysis, and I would reaffirm my belief that for the treatment of uncomplicated spastic contracture Stöffel's operation on the peripheral nerves remains the best method hitherto devised. Physiologically it is the nearest approach we can get to the natural means of regulating the strength of a muscular contraction.

A PROPRIOCEPTIVE REFLEX EVOKED BY STRETCHING.

Sherrington has shown that the tonic or postural activity of muscle is a proprioceptive reflex arising in the muscle itself. Further, Liddell and Sherrington have shown that the adequate stimulus for this reflex is stretching of the muscle. Thus, the tendency of the lower limbs to bend under the body-weight evokes a stretch reflex or tonic action of the extensor muscles, which persists as long as the stretching force is acting. This, then, is the mechanism by which the upright position of the body generally is maintained. Normally, postural activity is found only in the antigravity muscles—that is, those which constantly resist and counteract the action of gravity. The centre for this reflex is in the mid-brain, and it is known to be controlled and influenced by the labyrinths, the cerebellum, and the cerebral cortex.

I have dealt elsewhere [2] with the bearing of these facts upon the ætiology of postural deformities. Here I will only remind you that postural deformities are due to default of the normal postural activity of the muscles, and their treatment comprises: (1) correction of the deformity, if possible; and (2) re-education of the postural reflex.

For these purposes remedial exercises or gymnastics are extensively employed, consisting almost entirely of movements performed in various ways. And, in view of what has already been said, we may ask ourselves this question: If movement and posture are two entirely different mechanisms, what is the good of performing movements in order to educate posture? Experience proves that it is some good. Movement and posture, though distinct, are nevertheless closely associated. Postures are changed by movements, and change of posture is the adequate stimulus for postural activity. The important point is that it is not the movement per se, but the fixing of the postures attained by movement that constitutes the real exercise.

There is too much arm-and-leg wagging in the schemes of most gymnasts. Conventional Swedish exercises are based upon the erroneous idea that postural deformities are due to weak muscles, and it is sought to strengthen these muscles by making them perform repeated movements. An interesting experiment has been made in applying the technique of certain forms of dancing—so-called operatic dancing—to the re-education of posture. It is interesting because not only does it provide for most patients an attraction which is wholly wanting in ordinary remedial exercises, but the essence of this form of dancing is the posing or fixing of postures as distinct from the movements employed to attain them. A recasting of remedial exercises on these lines is long overdue.

MOVEMENT AND POSTURAL ACTIVITY.

But it is a mistake to think of posture as merely a state of immobility. Movement and postural activity are closely associated in many, if not most, of the ordinary actions of muscles. It has been shown that the simple stretch or myotatic reflex—as Sherrington calls it—consists of two parts: a short-lasting relatively intense phasic reaction, and a less powerful longer-lasting tonic reaction. So that, for instance, when weight is suddenly thrown upon a partly bent limb there is a brief powerful phasic contraction of the extensors to take up the sudden strain, and a prolonged tonic reaction to maintain the posture, or, in other words, to prevent the limb from bending. Thus at every step in walking and running and in many other movements a postural reaction is evoked which fixes the part, if only for a moment, in the position to which it has been brought.

Students are taught that the action of a muscle is the effect of approximating its origin and insertion. Thus, for example, the student learns that the action of the quadriceps is to extend the knee-joint. It is nothing of the sort. It is true that the quadriceps does extend the knee, but that is a very small part of its action. The great function of the quadriceps is to prevent the knee from bending. It is one of the great postural muscles of the lower extremity, and as its action is of considerable interest and importance to orthopædic surgeons it may well be taken as a type.

The functions of standing, walking, and running are essentially reflex in character. Of course, they are influenced in various ways by voluntary action; but essentially they are reflex. The postural reflex activity of the quadriceps is essential for all these functions. Failing this, the individual may be able to control the knee for a time by an extraordinary voluntary effort. But voluntary effort cannot be continued indefinitely, and when it fails, the muscle lets the knee down. This is the familiar condition of quadriceps insufficiency so common after injuries and diseases of the knee-joint, and it is noteworthy that powerful voluntary extension of the knee may be possible in cases of marked quadriceps insufficiency.

WHAT IS REFLEX ATROPHY?

In every serious injury or disease of the knee-joint rapid wasting of the quadriceps is one of the first signs to appear and the last to disappear. As we are now taking the quadriceps as a type, these remarks apply equally to many other regions of the body. So far as I know, no adequate explanation of this muscular atrophy has ever been suggested. It is much more than a mere disuse atrophy. It is obviously some active process. It has been called reflex atrophy; but what is reflex atrophy? There is no evidence of any specific trophic innervation of muscles.

I would suggest that there are two physiological factors responsible for this type of atrophy. One, a reflex inhibition of the postural or tonic activity of the muscle, about which there is no doubt whatever, and the other, a reflex excitation of the phasic activity of the same muscle, or, in other words, an attempt at reflex protective spasm.

Now, postural activity alone is able to maintain a state of tension for long periods with hardly any increase of metabolism, as in maintaining ordinary postures. With the help of postural activity a mild phasic activity also can be maintained very economically, as in the condition of decerebrate rigidity. But without the support of postural action prolonged phasic activity is a most extravagant form of energy and it leads to a rapid using up of the materials from which the energy is derived.

Some years ago Langley[3] suggested that the atrophy of paralysis following nerve injuries was due, not to disuse, but on the contrary to excessive activity of the muscle brought about by the traumatic excitation of the nerve. He did not mention the tonic or postural activity of the muscle, but, as this is abolished in peripheral nerve injuries, the same explanation may be applied also to this case.

TREATMENT MUST INCLUDE ADEQUATE STIMULUS.

It is worth while perhaps to consider for a moment the means which are commonly employed in treating quadriceps insufficiency, apart from the treatment of any underlying cause. The means are: (1) massage, (2) electrical stimulation, and (3) exercises consisting almost invariably of movements of extension of the knee. Each of these methods is capable of developing a wasted muscle, but not one of them is an adequate stimulus for the postural activity of muscle. Sherrington remarked upon the difficulty of producing anything approaching postural activity by artificial means, such as electrical stimulation. However, by what I regard as for the most part a fortunate accident, the mere development of a muscle makes it better able to regain its postural activity by taking natural exercise. But we have all met with cases of quadriceps insufficiency which have responded to treatment up to a certain point and then have ceased to improve. It is well then to remember that the adequate stimulus to the postural reflex is stretching of the muscle, provided, of course, that the muscle is able to resist it, and cases of quadriceps insufficiency will often show an astonishing improvement as soon as they are put on adequate resistance exercises.

It is instructive to put beside this the well-known clinical fact that stretching of a muscle, when it fails to evoke the corresponding reflex, as in a paralysed muscle, is a most injurious factor.

Sometimes, when the quadriceps muscle is paralysed, the operation of transplanting the hamstrings or some of them into the patella is performed with the idea that the transplanted muscles shall take the place of, and function as, the paralysed one. This operation is as physiologically unsound as it is generally useless. Such cases are often shown holding the knee extended or walking at surgical meetings. But the condition is at best one of complete quadriceps insufficiency. Postural activity is not normally found in the flexors of the joint, and no one has ever yet succeeded in imposing a postural reflex on a muscle transplanted from the flexor group. Therefore, when the patient forgets his knee and ceases to walk with voluntary effort, as he must do sooner or later, the muscles let him down. A similar objection applies also to some other tendon transplantation operations, especially in the lower extremity. For example, the peronei cannot be made to take on the postural action of the tibial muscles, nor can the tibials be made to take part in the stepping reflex which is normal to the peronei.

In contrast to these are some tendon transplantation operations in the upper extremity, notably that for musculo-spiral paralysis. Here the muscles are concerned with voluntary movements of precision, and the true substitution of one muscle for another is frequently possible.

There are many other questions concerned with muscular activity that one would like to hear discussed. The influence of muscular activity on bone growth; the significance of postural deficiency in rickets; the nature of organic contracture of muscle. What is cramp? Is not chronic constipation a symptom, rather than a cause, of postural deficiency? And if you think that here I have overstepped the bounds of orthopædic surgery, let me remind you (1) that there are many people who think that intestinal stasis plays an important rôle in orthopædic conditions, such as chronic arthritis; (2) that Sherrington has shown that the postural activity by which the muscular walls of the intestines and other hollow viscera adapt themselves to changes in the volume of their contents is precisely similar to the postural activity of the skeletal muscles by which the upright position of the body generally is maintained; and (3) that Arbuthnot Lane has said that he was led to his views on chronic constipation by his observations on scoliosis. Now, scoliosis is a subject about which orthopædic surgeons, rightly or wrongly, think they know something, and surely, if it is permissible to argue from scoliosis to constipation, an orthopædic surgeon may be allowed to hold an opinion.

The New Surgery.

In these rather scattered remarks I have tried to indicate what I believe to be the most distinctive feature of orthopædic surgery to-day. A change is coming over surgery. The old surgery, by long tradition based exclusively upon anatomy and pathology, is passing away, and its place is being taken by a surgery which takes into account also the functions of the living body. In other words, mechanical surgery—mere technique—is not everything, and physiology is coming into its own.

In this respect orthopædic surgery undoubtedly leads the way, and it is already far ahead of any other branch of surgery. This is the explanation of the long treatment—often miscalled after-treatment—which is so unpopular with the surgeon who looks for quick returns, but which is so essential a part of orthopædic methods. This also is the reason why fractures must be treated by orthopædic methods—whether by orthopædic surgeons or others. For a fracture is not only a broken bone, but a grave disturbance of function, and we know to our cost—or should I say, to our profit?—that the mere mending of a fracture in good position is not necessarily followed by perfect restoration of function.

The physiology of muscular action, with which I have dealt so imperfectly here, is but one instance of the fundamental relationship between physiology and orthopædic surgery.

Norfolk and Norwich Eye Infirmary.—This institution, which was founded in 1822, has now been amalgamated with the Norfolk and Norwich Hospital. The rearrangement provides for the maintenance of the Eye Infirmary as a separate entity administered by a committee appointed by the board of management of the hospital, and until the new premises which it is hoped to obtain are available the work will be carried on in the present building.

ON THE NATURE OF URINARY PROTEIN,

WITH SPECIAL REFERENCE TO CASES OF ECLAMPSIA.

By ALEXANDER HYND, M.A., D.Sc.,
CHEMISTRY DEPARTMENT, JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, AND PHYSIOLOGY DEPARTMENT, THE UNIVERSITY, ST. ANDREWS.

Owing to the very large number of hypotheses advanced concerning the ætiology of eclampsia, Zweifel some years ago aptly described it as "the disease of theories," and although, since then, as will be found in reviews of the subject in *Medical Science* (1921) and also by Hammett (1924) and by Bailey (1924), much work has been done and many suggestions offered to elucidate this perplexing condition, the ætiology of eclampsia still remains an unsolved problem.

Although cases of eclampsia have been described without any protein being detected in the urine, proteinuria is almost a constant finding, and is frequently very pronounced. The protein in such cases has usually been regarded as a mixture of serum albumin and serum globulin, with perhaps proteoses in addition, but definite proof of this seems lacking, and the experiments described in the present communication throw doubt on the statement.

About three years ago, in the course of an examination of the urine from a typical case of eclampsia, the author determined the optical activity of the urine and found it considerably less lævorotatory than was expected considering the protein content of the specimen. As search for the presence in measurable amount of other optically active compounds proved negative, and as removal of the protein yielded an inactive filtrate, the matter was more carefully investigated, as is detailed in the experimental part which follows.

Experimental Methods.

The experimental methods employed were identical in every case.

The urine was collected under a layer of toluene in glass-stoppered bottles, and as large a volume of urine as was available, usually about half a litre, was employed, but in Cases No. 1 and No. 3 as much as two litres were worked up, while the smallest quantity utilised was 270 c.cm. in Case No. 26. After separating any excess of toluene, the reaction of the specimen was adjusted, by the addition of sodium carbonate or acetic acid as the case required, till practically neutral to litmus paper, and the urine then filtered through a folded paper. As a rule, no difficulty was experienced in obtaining a perfectly bright clear filtrate, though a number of cases were encountered which gave turbid solutions. As this turbidity, being due to bacteria, was found to persist at the later stages, thus rendering polarimetric observations not only difficult but unreliable, all such cases were discarded.

The globulin and albumin present in the clear filtered urine were then fractionally precipitated by means of sodium sulphate at 40° C. As the protein content of the final solutions was calculated from nitrogen estimation by Kjeldahl's process, sodium sulphate was preferred as a precipitant to the more convenient ammonium salt, and the pure anhydrous sodium sulphate was used so as to avoid the large increase in volume which occurs with the crystalline salt. As Howe (1921) has shown that all the globulins are thrown out of solution when the sodium sulphate reaches a concentration of 21·5 per cent., sufficient of the finely powdered anhydrous salt was added to the urine to bring the concentration to approximately 22 per cent., and the mixture left in an incubator at 40° C. for some hours. The precipitated globulin was removed by filtration while warm, and the filtrate then saturated at 40° C. with anhydrous sodium sulphate to obtain the albumin. As the globulin fraction in practically every case represented only a small proportion of the total protein, attention was directed to the albumin fraction. The crude albumin, obtained as just described, was dissolved in cold water, the solution filtered, and the globulin and albumin fractionally precipitated with sodium sulphate at 40° C. as before. This process was repeated several times, usually six or seven, and as a rule after the fourth precipitation no globulin was present. The final precipitate of pure albumin (that is, free from globulin) was redissolved in water, and the solution dialysed until free from sulphate. The protein content of the resulting solution was then estimated and its optical activity determined.

The protein from two litres of urine from a case of typical eclampsia (see No. 1 in Table II.) was isolated, and the albumin separated from the globulin as described above. After dialysis against running tap-water for six days, then for two days against large volumes of distilled water, the solution of albumin was quite clear, only slightly brownish in colour, and free from sulphate as indicated by the absence of the ring test with barium chloride. The rotation of the solution was then determined, using a Hilger polarimeter with tripartite field, by which readings accurate to 0·01° are obtained. The mean of 12 readings for α in a 1-decimetre tube was −0·22°, and as the protein content by Kjeldahl's method (mean of four determinations, which all agreed closely) was 0·5806 per cent., hence the specific rotation of the albumin present in the urine was −37·89°.

Owing to the small amount of material available no attempt was made to obtain the albumin in the crystalline state, but the experiment was repeated with another quantity of urine from the same case, and a similar result was obtained—the value for the specific rotation of the albumin present in the urinary protein being −39·48°. As the preliminary examination of the urine and these two carefully conducted experiments with purified albumin clearly indicated the presence of an albumin with a lævo-rotation considerably less than the published values for serum albumin (see Table IV.), it was decided to determine the optical power of the albumin excreted in all the available cases of albuminuria in pregnancy, where the amount of protein was of a sufficiently high order.

TABLE I.—CASES DIAGNOSED AS "ALBUMINURIA OF PREGNANCY."

Case No.	Age in yrs.	No. of preg-nancy.	Month of preg-nancy.	Condition of patient.	Mam-mary gland.	Child.	Urine.	% protein.	$[\alpha]_D$ of protein.
									Degrees.
5	18	1	9	Œdema of feet and legs; B.P. 150/110.	—	Alive, slightly premature.	Catheter specimen; hyaline and granular casts.	1·27	−59·3
11	22	1	6	Considerable œdema.	—	Dead, premature.	Slight deposit of urates; no casts detected.	0·78	52·07
15	23	1	9	Nothing abnormal except proteinuria.	A.	Alive, mature.	Catheter specimen; turbid due to bacteria.	0·808 2·66	49·5 48·9
18	23	1	—	Marked œdema generally.	I.A.	Dead, mature.	Very dark-coloured urine.	0·274	65·7
21	24	1	9	—	A.	Alive, mature.	Catheter specimen; bacteria numerous.	0·31	51·02
25	26	1	9	—	—	Discharged from hospital undelivered.	Some R.B.C. and polymorphs.	0·166	54·2
27	19	1	9	Œdema of legs; eyelids puffy.	—		Urates and a few polymorphs.	0·265	49·05
30	—	1	8	—	—		Leucocytes and a few R.B.C.	0·226	53·21
31	—	—	8	—	—		Leucocytes; granular casts; a few uric acid crystals.	0·15	60·0
38	—	—	—	—	—	—	Numerous R.B.C. and acetone bodies present.	0·357	56·09
41	—	1	—	Had one fit after delivery.	—	—	Numerous hyaline and granular casts.	0·14	64·28
42	25	1	9	—	V.A.	Twins, alive and mature.	Brown colour; trace of bile pigment.	0·85	62·31

Experimental Results.

Twenty-six cases have now been examined in the manner just indicated. Twelve of these were diagnosed by the clinician in charge as albuminuria of pregnancy, and are tabulated in Table I., while 14 were described as of the eclamptic type and are tabulated in Table II.

In the cases of albuminuria of pregnancy (without convulsions), the specific rotation of the urinary albumin excreted ranged from −48·9° to −65·7°, with a mean value of −55·81°. Inspection of the cases in Table II. at once reveals the fact that the cases diagnosed as "eclampsia" are sharply divided into two groups, which for convenience may be referred to as the "low" and the "high" optical group respectively. In the "low" group, consisting of eight cases, the specific rotation of the urinary albumin ranged from −33·92° to −41·61°, with a mean value of −38·5°, while in the "high" group of six cases, the specific rotation varied from −49·4° to −58·67°, with a mean value of −56·37°. The possible significance of these values will be dealt with later.

The same method of examination of the urinary albumin was applied to five cases of proteinuria not accompanied by pregnancy. These are tabulated below in Table III. and include two typical cases of chronic nephritis and three of functional or orthostatic albuminuria—two of the latter being girls of about 12 years of age and the third a youth of 16 years. The value of the specific rotation of the albumin excreted by the kidney in these cases varied only slightly—namely, from −52·23° to −57·55°, with a mean value of −54·27°.

Optical Rotatory Power of Human Serum Albumin.

An experiment was then carried out to determine the optical rotatory power of human serum albumin, which had been subjected to identically the same treatment as the urinary albumin. For this purpose, Dr. X volunteered to provide the necessary blood, and 100 c.cm. was removed by vein puncture in the usual manner. After standing overnight, fully 50 c.cm. of clear serum were removed from the clot by means of a pipette and then centrifuged. The globulin present was then separated by the addition of the necessary amount of sodium sulphate following the same method as already described for the urine. Thereafter, the albumin was isolated from the globulin-free filtrate by saturation with sodium sulphate at 40° C. The precipitated serum albumin was removed by filtration, redissolved in water, and the process repeated four times. A portion of the solution of albumin then resulting was filtered through a No. 2 Chamberland candle and the optical activity and nitrogen content of the clear yellow-brown solution determined. From the Kjeldahl estimations, the protein content of the solution was calculated to be 1·285 per cent., and α in a 2 decimetre tube was −1·36°, so that the specific rotation of the serum albumin equalled −52·92°.

The remainder of the albumin solution was dialysed until free from sulphate. The resulting solution had a protein content of 5·121 per cent., and gave in a 1-decimetre tube $\alpha = -2{\cdot}79°$, so that $[\alpha]_D = -54{\cdot}47°$. The protein in solution was then precipitated by the addition of five volumes of alcohol, centrifuged, washed twice with alcohol and then with ether, and afterwards dried in a vacuum desiccator over calcium chloride. Approximately 1 per cent. solutions of the human serum albumin obtained as just described gave the undernoted rotations in the solvents indicated in Table IV.

TABLE II.—CASES DIAGNOSED AS "ECLAMPSIA."

Case No.	Age in yrs.	No. of pregnancy.	Month of pregnancy.	Condition of patient.	Convulsions.	Mammary gland.	Child.	Urine.	% protein.	$[\alpha]_D$ of protein. Degrees.
1	26	1	7	Face puffy; no œdema of ankles; had severe headache before convulsions started. Uninterrupted recovery.	10 fits; patient quite unconscious after the third fit.	I.A.	Dead, premature.	Considerable albuminuria with hyaline and granular casts. Chloride excretion low. Only a trace of protein 9 days after delivery.	0·5806 0·5825	−37·89 39·48
2	24	1	9	Patient became blind (temporarily).	No fits.	I.A.	Alive, mature.	Moderate albuminuria; only a trace of protein 2 days later.	0·748 0·4917	40·11 39·65
8	—	—	—	—	Post-eclamptic.	—	—	—	0·57	39·54
13	27	1	9	B.P. increased to 158 in spite of treatment. Mental condition abnormal for about 10 days after eclamptic seizure. A week later patient discharged quite recovered.	First fit 1 hour after delivery; had 22 fits.	I.A.	Alive, mature.	Catheter specimen; marked albuminuria. Deposit of urates.	1·06	33·92 34·97
22	35	3	7½	Œdema of feet and ankles; sudden amaurosis, severe headache and vomiting before fits began. B.P. rose from 140 to over 200 and continued high until delivery 3 weeks later. Discharged well a fortnight after birth.	3 fits; patient comatose afterwards.	I.A.	Dead, premature.	Granular and hyaline casts; considerable albuminuria. Trace of protein in urine 3 months later.	0·4567 0·9716 0·482	35·02 38·1 37·35
32	37	1	7½	Swelling of face and legs. B.P. 170 to 200. 2 fits. Labour induced. After labour urine output increased and œdema gradually disappeared. Discharged 11 days after labour, with no albumin.	1 fit before admission and 1 fit after admission, which lasted a minute.	I.A.	Alive, premature.	Triple phosphate crystals present. Numerous hyaline and granular casts. Acetone bodies present. Only very slight trace of protein a month later.	1·72 1·65 1·826	39·57 41·21 41·61
34	37	—	—	Œdema of ankles for 3 weeks. Headache and dimness of vision. B.P. 145/100. Severe headache before convulsions. Patient died 2 hours after delivery (hæmorrhage, toxæmia, and shock).	6 fits (antepartum).	I.A.	Alive, mature (died 2 hours after).	Urine had a very marked red-green fluorescence. Marked albuminuria with many R.B.C. and hyaline and granular and epithelial casts. Acetone bodies present.	1·65 1·397 0·6225	39·39 37·03 38·58
40	21	1	9	Patient admitted to hospital in comatose condition. Face cyanosed. Typical eclamptic convulsions. Mentally unstable for 3 weeks. B.P. 135–140 after delivery. Patient well nourished (instrumental delivery).	11 fits before delivery, 25 after.	—	Alive, mature.	Urine had a greenish-red fluorescence.	1·4	40·7
12	21	1	7	Pre-eclamptic. B.P. 158.	6 fits.	—	Discharged undelivered.	Deposit of urates; marked albuminuria; 4 days later only a trace.	2·372 2·439	57·32 55·76
14	28	1	9	Œdema under eyes. B.P. 158.	17 fits; first being 1 hour after delivery.	—	Alive, mature.	Catheter specimen; deposit of urates.	0·6277 0·9275	49·4 56·06
16	26	1	9	Œdema of legs and feet. B.P. 165.	8 fits; first fit immediately after delivery of head.	A.	Alive, mature.	Catheter specimen; deposit of urates.	0·5917	58·48
17	22	1	9	Œdema and headache. B.P. 210. Patient died probably of septicæmia.	9 fits after delivery.	I.A.	Alive, mature.	Catheter specimen.	0·1554	57·9
20	22	—	8	Patient unconscious. B.P. 150.	18 fits.	—	Alive, premature.	Catheter specimen; deposit of urates, and some casts detected.	1·687	58·67
29	27	1	—	Patient slightly confused. B.P. 165. Instrumental delivery. Developed chest symptoms and abdominal distension. Discharged after a fortnight with slight albuminuria.	A number of fits both before and after delivery (7 fits in all).	—	Dead, mature.	Triple phosphate crystals; a few W.B.C. and R.B.C. Granular casts.	0·2264	57·4

A. = active. I.A. = inactive. V.A. = very active.

Optical Rotatory Power of Cow's Lactalbumin.

As it was impossible to obtain sufficient human milk for the isolation and polarimetric examination of human lactalbumin, the optical rotatory power of cow's lactalbumin was determined. Two quarts of fresh dairy milk were allowed to stand for some time and the cream then removed as completely as possible by skimming. To the skimmed milk (1850 c.cm.) two volumes of water (3700 c.cm.) were added, and the casein precipitated by the gradual addition of acetic acid with stirring. To complete the precipitation 17 c.cm. 10/1 normal acetic acid were required. Sufficient toluene was then added to form a film on the surface of the mixture, which was left to settle overnight. The clear supernatant fluid was syphoned off and then evaporated to a tenth volume at 30° to 40° C. under diminished pressure. The concentrated solution, after filtration through a folded paper, was warmed to 40° C. and treated with sufficient anhydrous sodium sulphate to give a 17·5 per cent. solution. The resulting precipitate was filtered off and the filtrate saturated with sodium sulphate at 40° C. The precipitated proteins were then dissolved in about 300 c.cm. of water, and the fractionation of the globulin and albumin carried out as previously described for urine and blood serum. The albumin solution was then dialysed until free from sulphate, concentrated somewhat in vacuo at 30° C., and after filtration through a No. 2 Chamberland candle its rotation and protein content were determined. From the Kjeldahl estimation the protein content was 0·9108 per cent., and the mean of ten readings for α in a 1-decimetre tube was −0·375°, so that the specific rotation of cow's lactalbumin

$$= \frac{-100 \times 0{\cdot}375}{1 \times 0{\cdot}9108} = -41{\cdot}17^\circ$$

Nature of Urinary Protein.

Considerable attention has been directed to the nature of the protein excreted in the urine in different diseases, but apart from the well-known case of Bence-Jones's protein (1848), and the crystalline globulin isolated by Noel Paton (1892), the coagulable urinary protein almost invariably has been regarded as a mixture of serum proteins. Senator (1874) drew this conclusion as far back as 1874, and this view, supported as it was by later biochemical tests, has persisted in spite of the fact that the presence of other proteins in the urine has been established (van Noorden, 1907). Consequently greater attention was given to investigations, such as those by Cloëtta (1891) and more recently by Mandelbaum (1919) and others, in which attempts were made to correlate the various diseases exhibiting proteinuria with the magnitude of the albumin to globulin ratio. Work of this type has proved of little value (Noel Paton, 1890), but with our increasing knowledge of the proteins themselves and improvements in our methods not only of distinguishing the different types of proteins, which may occur in urine and to which Cavazzani (1921) has recently urged attention, but also of differentiating the several members of the same group of proteins, it seems likely that by a more careful study of the chemistry of the proteins excreted in the urine some light may be thrown on at least certain types of proteinuria, the clinical importance of which has been fully appreciated by all physicians for many years.

It is well recognised that in the study of the carbohydrates, the determination of the specific rotatory power as a means of characterising and establishing the identity of the various members of the group has proved of the greatest value. In spite of the adverse opinion of Robertson (1918), the use of the polarimeter in the study of the proteins would seem to be equally useful, and recent work points in this direction. Thus the important results obtained by the racemisation method, introduced by Kossel (1912) and elaborated by Dakin (1912) and others (1913), are dependent on the detection of changes in optical activity. Further, the observation of Sebelien (1885), made 40 years ago, that the specific rotations of the albumins in serum and in milk were different is supported by the most recent chemical analyses (Hartley (1914), Crowther and Raistrick (1916), and Woodman (1921)). In the experiments described in the present communication it is shown that the albumin excreted in the urine in different conditions has not always the same rotatory power. From th is the reasonable conclusion is drawn that the urinary albumin may vary in kind—a result which would be difficult to obtain by any other method, although recently Ishiwara (1923), by a modified Abderhalden reaction, has differentiated the protein appearing in the urine in pregnancy from those in chronic and acute nephritis. Moreover, the polarimetric method has the further advantage that it indicates the *possible* nature of the protein in question. Thus, the mean value for the specific rotatory power of the albumin excreted in the cases of "albuminuria of pregnancy" without convulsions (Table I.) was −55·81°; that in six cases of the "high optical" eclamptic group (tabulated in Table II.) was −56·37°; and that in five cases of albuminuria not associated with pregnancy (tabulated in Table III.) was −54·27°. All these values agree closely with those obtained by the author for human serum albumin prepared by an exactly similar process—namely, −54·47°, −52·92°, and −52·86° (see above). It may be noted also that the values, while considerably less than the exact figure, −62·83°, reported by Young (1922) for crystalline horse serum albumin, approximates the values given by Lewis (1922) and also the earlier values recorded in the literature for serum albumin. These are summarised in Table VI.

From Table VI. one is tempted to conclude that the albumin excreted in the urine in the conditions referred to above is probably identical with serum albumin. This is in agreement with the generally accepted view, but the results obtained by Sammartino (1922) must be considered. This worker applied van Slykes's method of analysis to differentiate between the protein excreted in amyloid disease and in Bright's disease. At first sight the values reported, as is evident from Table VII., would seem to fit in with the protein excreted in both conditions being a mixture of serum albumin and serum globulin; but the values obtained for the cystine fracticn not only differ widely in the two conditions (being four times as great in amyloid disease as in Bright's), but also amount to only a very small fraction of the cystine present in the blood proteins. It is difficult to reconcile this result with the close agreement of the optical activity of normal human serum albumin and of the urinary albumin excreted in the cases of albuminuria of pregnancy, chronic nephritis, and orthostatic albuminuria examined by the writer. Consequently, until further investigations of this type have been carried out on "purified" urinary proteins, it seems preferable to regard the albumin in these conditions as probably serum albumin. On the other hand, the urinary albumin in more than 50 per cent. of the cases of "eclampsia" investigated by the author is probably different from serum albumin, as in this "low optical" group the mean value for the specific rotation of the albumin present was found to be −38·5°. It would seem a significant fact that while in no case of proteinuria uncomplicated by pregnancy nor in "albuminuria of pregnancy" *without* convulsions has an abnormally low specific rotation for the urinary albumin been observed, in a large percentage of the eclamptic cases the albumin excreted in the urine is considerably less lævorotatory than serum albumin. Experiments have been in progress to determine the nature of this low optically active urinary albumin, but owing to the difficulty of obtaining material suitable for such investigation, so far no definite conclusion has been come to and further work will be necessary. The value of the specific rotation, however, suggests that the albumin may be lactalbumin. As far as the author is aware, no record exists of the specific rotation of human lactalbumin, but it probably does not differ widely from that of cow's lactalbumin, for which Sebelien (1885) quotes − 36·4° to − 36·98°. This value is a little lower than the more recent figure—namely, − 41·23°, given by Piettre (1924). The latter agrees closely with that recorded in the experimental part of this paper (− 41·17°). Though, as the result of biological tests, such as those carried out by Hamburger (1901), Schlossmann and Moro (1903), and Bauer and Engel (1911), it seemed to be established that the serum proteins were identical with the corresponding milk proteins, it has now been shown that while serum globulin is chemically identical with lactoglobulin, lactalbumin and serum albumin are distinct chemical individuals (Hartley (1914), Crowther and Raistrick (1916), and Woodman (1921)). This, as already indicated, is in agreement with the observed difference in the specific rotation of the two albumins.

Possible Significance of Lactalbumin in Relation to Eclampsia.

If, then, the suggestion that the "low optical" urinary albumin is lactalbumin be accepted, we have in certain cases of eclampsia an analogous condition to the lactosuria which not infrequently occurs in the later months of pregnancy or soon after labour. While corresponding to the symptomless albuminurias of pregnancy, there exists the fairly common glycosuria of pregnancy. However, while the presence of lactose in the blood and its excretion in the urine would do little or no harm to a patient, the presence in the blood-stream of lactalbumin, which must be regarded as a foreign protein, might entail grave danger. It may be that normally small amounts of lactalbumin find their way into the blood-stream during pregnancy, but that, as a rule, an immunity to this foreign protein is established. When this immunity is not established, or when a sudden release of a large amount of lactalbumin occurs corresponding to a "shock" dose of foreign protein, then eclampsia is the result. This view may suggest that eclampsia might be liable to occur in cases where a child dies at or soon after birth, or in cases where the mother for any reason does not breast-feed the child. No record of such an occurrence, however, is known to the author. If it be assumed not to occur, the fact is in perfect harmony with the theory suggested, for the mother in the majority, if not in all such cases, would be completely immunised against lactalbumin. Consequently, no eclampsia would ensue. The above view may also have a bearing in explaining the fact, now well established, that the incidence of eclampsia is much greater in primiparæ than in multiparæ.

The condition of eclampsia would thus be regarded as of the anaphylactic type, a view which has been strongly upheld by some workers, including Veit, Hofbauer, Roseman and Anderson, Gräfenburg and Lockmann, and also adversely criticised by others, amongst whom are Frank, and Heiman, and Zweifel, but, nevertheless, this view cannot altogether be ignored, for although Zweifel (1921) has stated that eclampsia cannot be considered as an anaphylactic reaction, that was only with respect to fœtal and placental proteins. Further, Levi (1922) has recently reported benefit produced by intramuscular injections of sterile milk in cases of pregnancy toxæmias including eclampsia.

A possible alternative explanation of the part played by lactalbumin is that in response to its introduction into the blood proteolytic enzymes would likely appear. By their action proteoses or other toxic decomposition products of the foreign protein would result, and unless the foreign protein and its hydrolysis products could be detoxicated by the liver or eliminated by the kidney rapidly enough, symptoms characteristic of eclampsia (or the pre-eclamptic state) would ensue. In this connexion it may be added that Hülse (1924) has presented evidence to prove that the increased blood pressure in eclampsia is caused by peptone in the blood; while Esch (1912) and Franz (1912) found in the serum and urine of eclamptics substances resembling anaphylactic poisons in their action and presumably derived from proteolysis somewhere in the body.

As recent work (Woodman, 1921) has shown that lactalbumin, like caseinogen, must be synthesised by the mammary glands, these glands are implicated in the causation of eclampsia. This idea, however, is not new. Sellheim (1909) suggested that eclampsia might possibly be due to toxins elaborated in the mammary glands, and Kastle and Healy (1912) advanced the view that parturient paresis (milk fever) in cows is caused by the absorption of toxic substances produced in the formation of colostrum and that the condition bears some resemblance to human eclampsia. Gessner (1921) also, in criticising Hofbauer's views on eclampsia, has pointed out that it also occurs in young cattle.

Further, unlike the proteinuria of, say, acute nephritis, that occurring in pregnancy is usually very materially influenced by the amount of protein in the diet. This fact, taken along with the well-known practice amongst farmers that a diet rich in protein is best for a good milk-supply, and the recent observations by Adair (1925) on the influence of diet on lactation in the human subject, would tend to support the view that the mammary gland is an important factor in the causation of eclampsia. In all the cases of the "low optical" group (Table II.), in which the condition of the breasts is reported, they are stated to be practically inactive. This inactivity may be explained by the stimulus for milk production coming too early, perhaps as the result of overactivity of the corpus luteum (Swale Vincent, 1924; Wallis and Williams, 1922), and thereby bringing about eclampsia. It is well to remember, however, in this connexion the observation by Hartwell (1921) that certain protein dietaries apparently render milk poisonous and finally check its flow.

The experiments described in this communication are only of a preliminary nature, but owing to the comparative rarity of eclampsia and the consequent difficulty in obtaining suitable material for such investigations the results so far obtained are published. The author is well aware, however, that much further work will be required and a greater number of cases investigated before the suggestions offered in the foregoing pages can be accepted as established facts.

Summary.

1. Experimental evidence is submitted which shows that the protein excreted in the urine in various conditions is not always identical.
2. In the 12 cases investigated of "albuminuria of pregnancy" without convulsions the specific rotation of the urinary albumin averaged −55·81°, and thus agreed with that found for human serum albumin under similar treatment—namely, −54·47°.
3. A similar close agreement in specific rotation—namely, −54·27°—was found in five cases of proteinuria not associated with pregnancy.
4. On the other hand, the 14 cases of eclampsia investigated were sharply divided into two groups, one group of six having an average $[\alpha]_D$ of −56·37°, and the other group of eight having an average $[\alpha]_D$ of −38·5°.
5. The optical activity of the albumin in the former group agrees well with that of serum albumin (−54·47°), while that in the latter approximates closely to that of cow's lactalbumin (−41·17°).
6. Accordingly, it is suggested (*a*) that in certain types of eclampsia the urinary albumin may be mainly lactalbumin; (*b*) that eclampsia may be an anaphylactic reaction due to the circulation in the blood of this foreign protein; and (*c*) that the mammary gland may be an important factor in the causation of eclampsia.

In conclusion, the author wishes to express his thanks to the staff of the James Mackenzie Institute for Clinical Research for assistance in various directions; also to Dr. A. E. Chisholm, of the Royal Infirmary, Dundee, for supplying the majority of the specimens; and also to Prof. P. T. Herring, of St. Andrews University, for much encouragement and advice.

A CASE OF ABDOMINAL LYMPHADENOMA.

BY L. R. SHORE, M.B. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ROYAL HOSPITAL FOR DISEASES OF THE CHEST, LONDON;

AND

W. A. YOUNG, B.SC., M.B., B.S. LOND.,
PATHOLOGIST TO THE HOSPITAL.

THIS case is recorded on account of the unusual features presented as regards diagnosis, distribution of the lesions, and mode of death.

A female, aged 26, was admitted to the Royal Hospital for Diseases of the Chest on August 5th, 1924, from the Willesden General Hospital, whence, having been observed to be febrile and to lose weight, she was transferred for observation as to her chest.

She had suffered for about a year from pain in the right thigh and leg, in the sacral region, and occasionally in the left thigh. She also complained that some curvature of the back had developed.

Condition on Admission.—The patient was thin and pale. Temp., 102·8° F.; pulse, 144; resp., 22. Mucous membranes were of good colour, no cyanosis or jaundice, there were some small deep ulcers on the face. Tongue red and glazed; no glandular enlargement in the neck. Pulse regular, blood pressure 100 mm. Hg systolic and 75 diastolic. Heart and lungs presented no abnormal physical signs. The abdomen was rigid and difficult to palpate, particularly in the upper part. A few hard glands in the right groin. A definite kyphosis of the lower dorsal and lumbar region was present with rigidity, but no redness or tenderness. No sensory changes in lower limbs or trunk; nothing significant in reflexes. Urine, sp. gr. 1010, acid, contained trace of albumin but no sugar. There had been amenorrhœa for 12 months. The findings did not suggest disease of the chest or central nervous system. The patient was quite definite that the spinal deformity was of recent (within six months) development.

Course and Progress.—Temperature fluctuated between 98° and 101°; pulse-rate varied from 144 on admission to 92; respiratory-rate from 20 to 26.

Blood Count (August 9th, 1924): Hæmoglobin, 77 per cent.; red blood corpuscles, 4,600,000, some anisocytosis and polychromatophilia. White blood corpuscles, 23,000 with differential count: Polymorphs, 91 per cent. (20,930 per c.mm.); small lymphocytes, large lymphocytes, and large hyaline, each 3 per cent. (690 per c.mm.); eosinophiles and basophiles, 0.

Urine.—No casts. On culture *B. coli*, *B. proteus*, and an organism resembling a fæcal streptococcus were recovered.

There were occasional attacks of severe pain down the back of the thighs.

Pelvic Examination revealed no abnormality. A swab taken from the cervix uteri showed pus cells with a streptococcus as the prevailing organism.

X Ray Examination of the Spine by Dr. C. Gouldesbrough showed abnormalities of ninth and eleventh dorsal and fourth lumbar vertebræ, which were wedge-shaped. "The outlines of the vertebræ are very regular and do not suggest tuberculous caries so much as mechanical pressure." Rarefaction of the body of eleventh dorsal was noted. On August 20th, 1924, the right side of the face was noted to be puffy. Albumin was present in the urine in small quantity. On the 28th the face and ankles were definitely œdematous, and the urine showed increase of albumin. From the 31st the daily quantity of urine varied from 12 to 28 oz., and the albumin rose from $\frac{1}{4}$ parts per mille (Esbach) to 9 (Sept. 2nd), remaining afterwards fairly constant at that figure. Microscopical examination of urinary deposit showed pus cells and leucocytes—small epithelial cells and a few doubtful granular casts. Urea-concentration test indicated a definite urea retention. On Sept. 13th hyaline and coarsely granular casts were found with some pus and epithelial cells. The abdominal condition remained much as before, the liver was felt and was apparently tender.

The condition was provisionally diagnosed as amyloid disease, supervening on a chronic streptococcal infection of the vertebral column, or alternatively neoplasm of the vertebral column. The œdema continued, vomiting, dyspnœa, and headaches supervened, and the patient died in coma Sept. 21st, 1924.

By the courtesy of Dr. Vickery, resident medical officer of Willesden General Hospital, we learned that while there the temperature ranged from 98° to 100° with occasional evening rise to 101°. There had been no albuminuria.

Post-mortem Appearances.

External Appearance.—Generalised œdema, marked abdominal distension, several small facial ulcers, no palpable enlargement of glands.

On Section.—1. Thorax: About 2 pints clear brownish fluid in each pleural cavity; lungs showed very marked collapse; no pleurisy or pleural scarring. On section lungs contained no excess of blood or any œdema fluid; there was a purulent exudate in bronchi. Heart: Small excess of clear pericardial fluid, very slight roughening of pericardium over left ventricle; valves competent; muscle poor. 2. The abdomen contained about three pints of yellowish-brown fluid containing a few flakes of fibrin. Some cheesy fibrinous exudate over the pelvic floor; no inflammation of uterus and adnexa. The liver showed a large nodular, pale yellowish area on its anterior surface, and was generally enlarged, extending well below (2 inches) the costal margin. On section this pale area, which was about 3 inches in diameter and irregular in outline (with small outlying area), extending deeply into liver, and resembled a malignant tumour. The spleen of normal size or rather smaller. On section was a typical "sago-grain" spleen, the grains of considerable size, and the intervening tissue dark purple (iodine test negative). The kidneys were of medium size and of extreme pallor, in colour slightly yellowish-grey. They stripped with some difficulty. On section this pallor was still more noticeable, the colour being grey-white with some yellowish streaks in the medullary region. Iodine test negative. The pancreas was large and unususally tough. Lymphatic system: All lumbar and sacral glands were densely matted together and to surrounding structures, exceedingly tough and hard, but only moderately enlarged. The matting appeared to be of the nature of a chronic inflammatory fibrosis rather than malignant extension, the great veins being attached to, but not infiltrated by, the glands. Some glands were firmly fixed to the anterior ligaments of the lumbar spine in the same way. No other gland groups appeared to be affected. Spinal column: The eleventh dorsal vertebra was about half the thickness of adjacent vertebræ. The discs showed no abnormality, but the body of the vertebra was soft and pulpy. Adjacent vertebræ were not affected, but the body of the second lumbar vertebra was also found to be soft to the knife. (The eleventh dorsal vertebra was removed for section.)

Histology.

Examination of sections from the lumbo-sacral glands, the spleen, and the deposits in the liver and bone show the characteristic picture of lymphadenoma of the acute type ("malignant type" of some authors). At the growing edge of the deposits in the liver the granuloma showed most clearly the varied nature of its cells, many endothelioid cells with some giant endothelioid cells containing one to three large irregular hyperchromatic nuclei, reticular cells, a few small lymphocytes, fairly numerous eosinophiles, and some plasma-cells. The spread in the liver was primarily from Glisson's capsule along the inter-lobular connective tissue, and then by direct extension into the lobules themselves. At the edge of the granulomatous areas the liver cells showed shrinkage and degeneration, and marked increase of the supporting and endothelial cells and deposition of pigment. In the walls of a few of the capillaries small amyloid deposits were found.

A similar appearance was found in the more outlying glands of the lumbo-sacral group (apparently those most recently infiltrated). But in the more central glands of the group, which were densely matted together, considerable fibrosis had taken place. Sections of the spleen showed enormous increase of reticular structures, generalised fibrosis, and collagen deposition. In the fibrous tissue a few endothelioid cells were present, and in the less fibrous areas the typical cells of the granuloma were found. Areas of pigmentation and some small amyloid deposits in relation to capillaries and fibrosed Malpighian corpuscles were also observed.

Sections of the body of the eleventh dorsal vertebra show considerable bone destruction, although few active osteoclasts were seen. The bone and marrow appear to be largely displaced by a scantily cellular tissue with a few areas of lymphocytic infiltration containing some endothelial cells, reticular cells, and "giant cells" (the latter quite distinct from the multinucleate cells of the marrow). The nature of the granulomatous infiltration was less obvious here than elsewhere.

Sections of the kidney show advanced amyloid degeneration of the walls of the glomerular capillaries and of the capillaries running parallel with the pyramidal tubules. The kidney shows also granular and cloudy changes in the tubular epithelium and a considerable increase of inter-tubular connective tissue, partly fibrous in nature but rather more cellular than the interstitial tissue of chronic interstitial nephritis. This tissue showed early endothelial hyperplasia and may possibly represent an early infiltration similar to that found in the liver.

Conclusions.

Diagnosis by examination of an excised gland is not available in the "abdominal form" of Hodgkin's disease because only deep lymphatic glands are affected. In this case the clinical picture was obscured by a polyleucocytosis (probably of secondary origin), radiological appearances and postural changes of an uncommon nature, and the late onset of renal amyloidosis. Bony infiltration and amyloidosis are both recognised sequelæ of Hodgkin's disease, although comparatively uncommon.

DONCASTER INFIRMARY.—It is proposed to build a new infirmary at a cost of £300,000. The existing buildings, which contain 65 beds, have been twice enlarged in the last 20 years, but are still so inadequate that many patients have to be sent to Sheffield, Leeds, Hull, and Nottingham. When the infirmary was established in 1792 the population of this area was 15,000; it is now nearly 200,000. The miners and railway men, who form 80 per cent. of the working population, together with the glass-workers, have submitted to a weekly deduction from their wages towards a building fund, and their payments amount to £12,000 a year.

SHEFFIELD HOSPITAL SITE.—Sheffield recently has been fortunate in securing Norton Park as its future hospital site. This park, situated in an elevated position well above the city, is 120 acres in extent, and within 12 minutes ambulance service of the city centre. The value to the hospitals of this site has been considerably enhanced by the generous gift from Councillor and Mrs. J. G. Graves, of Sheffield, of the remaining 154 acres of adjacent land and wooded estate, making an open space of 274 acres, thus safeguarding for all time the future voluntary hospitals of Sheffield from any proximity to industrial and residential buildings.

Clinical and Laboratory Notes.

A NOTE ON THE GLOBULIN AND COLLOIDAL GOLD REACTIONS OF THE CEREBRO-SPINAL FLUID

AFTER THE MALARIAL TREATMENT OF GENERAL PARALYSIS OF THE INSANE.

By J. ERNEST NICOLE, L.M.S.S.A. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER, LANCASHIRE COUNTY MENTAL HOSPITAL, WINWICK;

AND

JOHN P. STEEL, M.B., CH.B. EDIN.,
ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

DURING the observation of 80 cases of general paralysis treated with therapeutic malaria, it has been found expedient to re-examine the cerebro-spinal fluid in 25 cases at varying dates after the termination of the pyrexia. Although recent observers, including McAlister [1] and Houston and Armstrong,[2] have stated that little or no alteration in the reactions of the cerebro-spinal fluids is to be seen, our findings hardly seem to support their views, at least in so far as the globulin and colloidal gold tests are concerned.

From the results we quote below it will be seen that more than half the cases mentioned now show a negative reaction to the globulin test, whereas all showed a positive result before treatment.

As regards the colloidal gold reaction, even allowing for the human element in taking the readings, the changes more or less correspond in their occurrence with the conversion of a positive globulin reaction into a negative one; furthermore, the change has not only been the "displacement to the left and upwards" mentioned by Pappenheim, but is also of the nature of a conversion of a true paretic reading to that more usually associated with a diagnosis of cerebro-spinal syphilis. (Table I.)

TABLE I.

Case.	Before treatment.		Period since treatment.	After treatment.	
	Coll. gold.	Glob.		Coll. gold.	Glob.

18	5555541000	,,	15 ,,	0123443100	,,
19	4555543300	,,	12 ,,	0255544321	Pos.
20	5555554100	,,	15 ,,	4555553311	,,
21	5555555543	,,	13 ,,	0125543300	Neg.
22	1125555510	,,	14 ,,	5555544300	Pos. weak.
23	4555555443	,,	13 ,,	4555544300	Pos.
24	5555555430	,,	7 ,,	5555555432	,,
25	5555554200	,,	6 ,,	4555553220	,,

It must be pointed out, however, that changes in the globulin and colloidal gold reactions do not necessarily correspond with the presence or absence of definite clinical improvement. (Table II.)

TABLE II.

Reaction.	Physical condition.		Mental condition.	
	Improved.	Not improved.	Improved.	Not improved.
Altered	8	6	5	9
Not altered ..	7	4	6	5

Of the ten cases shown as not physically improved it should be pointed out that six were admitted in fair health and are still in that condition.

Although we do not attempt to draw any conclusions from our findings, it may be of interest to note that of those cases admitted in an advanced condition of general paralysis (showing progressive dementia and faulty habits coupled with physical debility), out of a total of 12, 8 have shown no appreciable alteration in the reactions of the cerebro-spinal fluid after treatment with malaria. On the other hand, out of the 13 early cases, 10 have shown definite changes in these respects.

We are indebted to our medical superintendent, Dr. F. M. Rodgers, for permission to report our findings.

TRAUMATIC LESION OF THE CAUDA EQUINA; LAMINECTOMY; RECOVERY.

By E. ROCK CARLING, F.R.C.S. ENG.,
SURGEON TO WESTMINSTER HOSPITAL;

AND

HILDRED CARLILL, M.D. CAMB., M.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL.

THIS case of injury to the cauda equina presents several features of interest that render its record desirable.

The patient, a stone-mason, aged 45, fell 40 feet to the ground in a scaffold accident on Sept. 3rd, 1924. He was admitted at once. In addition to severe shock he had extensive contusions over the lower ribs and in the lumbar region, and he had a Pott's fracture on the left side and some fractured metatarsals on the right side. The abdomen rapidly became distended and tender, and there was vomiting and hiccup. The lumbar spinous processes appeared to be somewhat irregular and the power of the lower limbs impaired, but an exact investigation was rendered difficult by reason of the fractures.

The following day the man had retention of urine and complained of severe lumbar pain, and on Sept. 5th there was loss of control of both urine and fæces. On the 6th the lumbar cerebro-spinal fluid was found to be intimately mixed with blood.

Examination on the 7th showed weakness of the lower limbs but no palsy at any joint and no abnormality of cutaneous sensibility. Tuning-fork vibrations were correctly perceived. The knee-jerks were normal, the ankle-jerks were abolished, the calf-jerks were normal. The epigastric and abdominal reflexes were all normal. On the 10th there was paresis of the lower limbs. The knee-jerks were exaggerated equally and both ankle-jerks remained abolished. The abdominal reflexes were all healthy, but the plantar responses and the superficial anal and bulbo-cavernosus reflexes were found to be all absent. Erections had not occurred since the accident. Sensibility to every variety of stimulus was normal throughout. The lumbar cerebro-spinal fluid contained still a little blood. A lesion of the cauda equina, below the second lumbar segment, was diagnosed and a radiogram showed a fracture of the first and second lumbar vertebræ.

Laminectomy was performed on Sept. 11th and disclosed much extra-thecal blood clot. Within the theca there was no blood clot and the cord, which did not pulsate, appeared to be otherwise unaffected. A catheter was passed freely upwards and downwards within the theca. The bony canal was diminished in its antero-posterior diameter at the site of the fractures by a posterior displacement of the bodies of the last two dorsal and first lumbar vertebræ. The pressure on the cord had been exerted, so far as could be ascertained, opposite the second and third lumbar segments, causing it to be bruised on its anterior aspect. Not until the firm, partly organised, decolorised extra-dural clot had been completely removed did the cord pulsate.

Two days after the operation the man complained of tingling and shooting pains in the lower limbs. There was already some return of power in the legs and by Sept. 24th they were still stronger. On Oct. 1st the ankle-jerks were still abolished. During the first week of October convalescence was interrupted by bronchitis and slight mental derangement. He improved after phlebotomy. On the 8th he passed urine naturally for the first time since the accident, and by the 14th there was still further improvement in this respect and in his general condition. On the 20th the ankle-jerks were elicited and on the 23rd he was allowed out of bed. He walked for the first time on Nov. 10th, and he now had fair control of both sphincters. This control was almost complete by Dec. 5th, and on the 8th he was walking normally on the level and on stairs and without pain. The bulbo-cavernosus reflex was now present on the left side, absent on the right. The superficial anal reflex was absent. Erections had not returned. He was discharged on Dec. 8th, 1924, on the eighty-ninth day after operation.

He was again seen on June 13th, 1925. Apart from total impotence, slight delay in commencing micturition and the occasional leaking of a little urine at the end of the act, and some precipitancy of defæcation, he was well, but he complained of a little pain in the lower spine. Knee- and ankle-jerks were healthy. The epigastric, abdominal, cremasteric and plantar reflexes were all normal. The bulbo-cavernosus reflex on each side was normal and the superficial anal reflex had recovered its activity.

INTESTINAL HÆMORRHAGE CONTROLLED BY COAGULEN (CIBA)

DURING A SEVERE ATTACK OF TYPHOID FEVER.

BY L. C. DUNDAS IRVINE, M.R.C.S. ENG.,
SURGEON LIEUT.-COMMANDER, R.N.V.R.

THE knowledge of an easily administered and reliable styptic is a great mental comfort in emergency, so I am placing on record an instance of the successful use of coagulen (Ciba) in a case of typhoid with intestinal hæmorrhage. Coagulen (Ciba) is the name given to a preparation of fibrin ferment, the properties of which were established[1] by Dr. Fonio in Kocher's clinic in Berne. It is now marketed by the Clayton Aniline Co., and its rapid action in two striking cases, one of tonsillar hæmorrhage, the other of hæmoptysis, has been recently recorded.[2] In the following case the drug was instrumental in saving the patient's life.

E. L. C., aged 19, contracted typhoid on the continent of Europe early in July, 1925, and the case came under my care on July 24th. It was a severe attack, characterised, as also in her sister, who simultaneously contracted the disease, by the high initial temperatures. On August 2nd the temperature, which had dropped after much struggling from the region of 105° to 103° F., shot up again to 105° and a sharp hæmorrhage made itself evident. A dose of 1·5 c.cm. of coagulen (Ciba) was given intramuscularly and repeated four hours later. Though a large quantity of altered blood and blood-clot was evacuated during the next two days there was no more fresh bleeding. On August 17th there was another hæmorrhage, even more severe than the first, without the rise in temperature that had announced the former. Two more intramuscular injections of 1·5 c.cm. at four-hourly intervals were given and again the bleeding ceased and was no more repeated. A careful watch has been kept ever since for any signs of venous thrombosis, but there has been none, and the patient's convalescence has progressed far enough now, though she is still in bed, to justify the hope that that tiresome complication will not manifest itself.

I have used coagulen (Ciba) in a fair number of cases of hæmorrhage from various causes without it once failing me, and it is satisfactory to record its successful use in a patient desperately ill without any unpleasant after-effects or reaction.

SECTION OF SURGERY.

THE TEACHING AND PRACTICE OF SURGERY.

THE first meeting of this Section for the session was held on Oct. 21st, when Sir **LENTHAL CHEATLE**, the new President, delivered an address on the Present State of the Teaching and Practice of Surgery. He divided his subject into three main portions—research, specialties, and treatment.

Research.
